SHUTTLE OFT LEVEL C
NAVIGATION REQUIREMENTS

ONORBIT

1.0 INTRODUCTION

1.1 PURPOSE

This document provides Level C detailed requirements for the orbital operations computer loads, OPS 2 and OPS 8. These requirements represent the total Onorbit/Rendezvous Navigation baseline requirements for the following principal functions.

- A. Onorbit/Rendezvous Navigation Sequencer
- B. Onorbit/Rendezvous UPP Sequencer
- C. Onorbit/Rendezvous Navigation
- D. Onorbit Prediction
- E. Onorbit User Parameter Processing
- F. Landing Site Update

The Onorbit/Rendezvous Navigation Baseline was last issued on May 1, 1979 as FSSR Version C; i.e., as SD 76-SH-0006C. That publication absorbed Version B (published November, 1977) and also the January 19, 1979 and May 1, 1979 block updates.

This publication reflects Version C of the Onorbit/Rendezvous Navigation FSSR plus the following page change numbers (PCN's) written against Version C:

- A. PCN 1 - an August 15, 1979 update.
- B. PCN 2 - a January 15, 1980 update.
- C. PCN 3 - a May 15, 1980 update.

The following is a list of CR's that were incorporated into this document with Version C, PCN 1, PCN 2, and PCN 3.

CR 2599B	CR 12374	CR 19373B
CR 12164	CR 12419	CR 19445A
CR 19167B	CR 12442A	CR 19446A
CR 12266A	CR 12456A	CR 19472A
CR 12285	CR 12478	CR 19571A
CR 12286	CR 12545	CR 19655A
CR 12326	CR 12623	CR 19361A
CR 12661	CR 12803

1.2 ORGANIZATION AND STRUCTURE

The organization of the November 1977 baseline was extensively revised with its Version C in order to structure the text closely to the suggested implementation given in the flowcharts of appendices B, C, D, E, and F. In order to accomplish this task the following guidelines were developed for the organization and text structure of this document.

Guideline 1. - Each flowchart in the Appendices B, C, D, E, and F will be classified either as a subroutine, function, or code. The subroutine or function classification will be given for the following reasons:

- (1) to avoid duplication of code,
and
- (2) to clarify the function of the flowchart with text and Input/Output (I/O) tables.

Guideline 2. - The requirements for each subroutine and function will be described in one and only one text section of chapter 4.

A flowchart labeled code is to be regarded as in-line code and will be explained in the text section belonging to the subroutine in which the code is located. If a subroutine calls another subroutine or executes code, the CALL or EXECUTE statement will appear in the associated text. Text section descriptions will closely follow the associated flowchart.

Guideline 3. - Those text sections describing subroutines and functions will have Input/Output (I/O) tables.

The determination of Input and Output variables to a given subroutine can be quite subtle so the following simplistic definitions are proposed.

Input Variables

- (1) Those variables needed to be input to the routine for the proper execution of the subroutine or function, e.g. variables used in computations, variables used in logical tests both implicit and explicit, etc.
- (2) Variables in the INLIST to the subroutine.

Output Variables

- (1) Those computed variables needed by other routines.
- (2) Variables in the OUTLIST of the subroutine.
- (3) Variables computed for the DOWNLIST.

Guideline 4. - Each I/O table will have the format given in Figure 1.2-1. The variables in the INLIST and OUTLIST as arguments to the subroutine have only local names so a special arrangement should be made for these variables by listing them under a special section in the Input/Output (I/O) tables with a slightly different format.

INLIST/OUTLIST*		INPUT SOURCE	OUTPUT DESTINATION
INTERNAL NAME	EXTERNAL NAME		
R	R_FILT	Subroutine A	
	R_TV	Subroutine B	
H	ALT		Subroutine A
			Subroutine B
VARIABLE NAME			
V_FILT		Subroutine A	Subroutine B
R_TV		Subroutine C	

Figure 1.2-1.- I/O table format.

*NOTE: If the subroutine has no INLIST or OUTLIST then the INLIST/OUTLIST portion of the I/O table will be omitted.

Input variables may be obtained by looking at the input source column and output variables may be obtained by looking at the output destination column.

Guideline 5. - Text sections describing Principal Functions will also have Input/Output Tables.

The Principal Function (PF) I/O will show Input/Output flow between principal functions. The Principal Function I/O variable definitions will be consistent with those used to define I/O variables for subroutines. The Principal Function I/O tables will have the format given by Figure 1.2-2. Local destination refers to the local subroutine needing the PF input variable. Local source refers to the local subroutine outputting the PF output variable.

VARIABLE NAME	PRINCIPAL FUNCTION SOURCE	LOCAL DESTINATION	PRINCIPAL FUNCTION DESTINATION	LOCAL SOURCE

Figure 1.2-2.- Principal function I/O table format.

Since one of the more important interfaces between Principal Functions is involved with the "snapping" of data, it is proposed that this type of interface be indicated in a special way by the Principal Function I/O tables. Variables involved in the IMU and Attitude Data Snap (section 4.2.2.1) or the Rendezvous Sensor Data Snap (section 4.2.2.2) will be given the variable name used by the appropriate SOP when that SOP supplies the variable for the Data Snap. The local destination will be labeled DATA SNAP and the reader will be referred to the text section explaining the Data Snap. This section will have tables showing the correspondence between the external SOP variable names and the variable names used by the Principal Function for the "snapped" variables.

Guideline 6. - In the November 1977 baseline document there was quite a bit of redundancy in the information supplied by various tables. For example, precision requirements were frequently given whenever a variable was listed in an I/O table. While such a practice can be defended on the grounds of clarity and convenience, it can lead to inconsistencies between tables. Subsequent versions of the FSSR have employed central tables which collate tabular information in one and only one place. It is intended that the variable list in Appendix A as well as the variable lists of Appendices C, D, E and F now include all of the following information.

1. Variable Name - The HAL variable name used in the flowcharts.
2. Precision and Type - This column will contain the following symbols:

DF: double precision floating point scalar

DF(n): double precision floating point n-dimensional array

DF(n,m): double precision floating point n by m matrix

SF: single precision floating point scalar

SF(n): single precision floating point n-dimensional array

SF(n,m): single precision floating point n by m matrix

I: integer (unless otherwise specified all integer quantities are assumed to be single precision)

Bit: variable having only the values 0 or 1

Char: character string

3. Initialization category - This column will categorize the OPS-2 navigation parameters for initialization purposes.

Mission Dependent (I-LOAD)

Design Dependent

Level A constants

Hard Codeable

OPS Transition parameters

Other required initial values

4. COMPOOL or Local - This column will specify whether or not the variable is local or is required to be in COMPOOL.
5. Description - This column will provide a definition of the parameter.
6. Initial Value - This column will supply the numerical value for the Design Dependent and Hard Codeable parameters as well as other required initial values.
7. M/S ID - This column provides the M/S ID numbers for the variables in the PF I/O Tables.
8. Uplink/Downlist - This column will state which variables are uplinked or are to be downlisted.

Guideline 7. - Information that can be found in the Central Tables will not be duplicated in any other table unless necessary.

Corollary to guideline 7 is that there will be no collated Mission Dependent Parameter List (I-LOAD) and no collated Downlist. Rather, these variable lists can be gleaned from the information contained in the Central Tables in the Appendices.

1.3 THE CHANGE LOG

The changes made to the May 1979 baseline through PCN 2 to Version C of this document are tabulated in the following change log (table 1.3).

TABLE 1.3.- ONORBIT/RENDEZVOUS CHANGE LOG

Section	Section title	Description of change
1.1	Purpose	CR's added to list of CR's incorporated into this document.
1.3	Change Log	Change log for Nov. 1977 baseline document deleted. New change log begun for the May 1979 baseline.
3.3.4.1	Requirements Overview	Added description for new requirements on predictor.
3.3.4.2.1	Onorbit/Rendezvous Assumptions	Added and modified descriptions of nav's usage of <ul style="list-style-type: none"> o predictor o crew-controlled flags o state vector propagation scheme
3.3.4.2.2	Rendezvous Only Assumptions	Modified description of the covariance propagation rate.
4.1	Onorbit/Rendezvous Navigation Sequencer Principal Function	Sequencer task completely redesigned to take advantage of change to schedule NAV at only one state vector propagation rate -- DT_NAV_STATE_PMP. Interface with REL NAV display for the filter rate switch deleted. USE_IMU_DATA flag deleted as output to NAV and OBS_UFP. DOING_REND_NAV flag added as output to NAV and OBS_UFP. An IMU_THRESHOLD -- DA_THRESHOLD -- deleted as output to NAV. Significant changes made to principal function I/O table. Logic redesigned to account for NAV needing to be scheduled at only 1 state vector propagation rate. Logic deleted for setting USE_IMU_DATA, DA_THRESHOLD, and N_CYCLE.
4.1.1	Sequencing Operations and Major Mode Transitions	

TABLE 1.3.- ONORBIT/RENDEZVOUS CHANGE LOG

Section	Section title	Description of change
		Logic deleted for responding to DO_FLTR_SLOW_RATE switch and setting the DOING_FLTR_SLOW_RATE flag.
4.1.1.1	REND_NAV_EXIT	Equations added to turn off rendezvous flags.
4.1.1.2	NAV_EXIT	New section -- added as part of the sequencer redesign effort.
4.1.2	OPS_2_OR_8_INITIALIZE	Changed predictor step size for this task.
		Deleted setting powered flight navigation flags and the USE_IMU_DATA flag.
4.1.2.1	Orbiter State Vector Reset	Changes made to I/O table.
4.1.2.2	Rendezvous Navigation Initialization	Logic modified to delete directly calling the predictor and to schedule instead the state vector prediction task.
		Equations added for turning on two rendezvous navigation flags.
		Call to COV_LAST_RESET deleted (the call was moved to REND_COV_INIT).
		Changes made to I/O tables.
4.1.2.2.1	Covariance Matrix Initialization	Added call to COV_LAST_RESET.
4.1.2.2.1.3	Covariance Matrix Parameters Reset	New section number for existing module.
		Changes made to I/O tables.
4.1.2.2.2	Target State Vector Reset	Changes made to I/O tables.
4.1.2.2.3	Covariance Matrix Parameters Reset	Section number deleted. Module moved to section 4.1.2.2.1.3.

TABLE 1.3.- ONORBIT/RENDEZVOUS CHANGE LOG

Section	Section title	Description of change
4.2	Onorbit Rendezvous Navigation Principal Function	<p>Logic added to compute value for N_CYCLE rather than depending upon obtaining the value from the sequencer.</p> <p>Changed names for the star tracker angles output by the S.T. SOP.</p> <p>Change made to interrogate the DOING_REND_NAV flag from the sequencer to determine when to exercise rendezvous navigation.</p> <p>Interface established with IMU_ALIGN_DISPLAY to access crew-input IMU threshold.</p> <p>Interface deleted with sequencer for obtaining an IMU threshold value.</p> <p>Interface deleted with sequencer and ORB_UPP for the USE_IMU_DATA flag. Internal logic modified to always set this flag.</p> <p>Significant changes made to principal function I/O tables.</p>
4.2.1	Navigation Control	<p>Sequence changed to execute state and covariance update functions prior to the state vector propagation function.</p> <p>Change made to key on the DOING_REND_NAV flag to determine when to exercise the rendezvous navigation logic.</p> <p>Logic added to compute N_CYCLE based on the crew-set DO_FLTR_SLOW_RATE switch.</p> <p>Changes made to I/O tables.</p>

4.2.3	Position and Velocity State Propagation	Section moved to section number 4.2.4.

TABLE 1.3.- ONORBIT/RENDEZVOUS CHANGE LOG

Section	Section title	Description of change
		Change made to delete the call to the free flight propagator -- ONORBIT_PRECISE_PROP -- and call the SUPER_G propagator for both Orbiter and target state propagation for both free and powered flight.
		Logic added to make use of the IMU_NAV_ACCEL_THRESH set by the crew.
		Logic modified to set the USE_IMU_DATA flag on each navigation cycle.
		Logic modified to key on the DOING_REND_NAV flag to determine when target vehicle propagation is required.
		Logic modified to use the powered flight potential model only when the computed Orbiter acceleration exceeds MEAS_THRESHOLD.
		Changes made to I/O table.
4.2.3.1	Precision Propagation	Section deleted.
4.2.3.1.1	Integration of the Equations of Motion	Section moved to section number 4.3.1.
		Changes made to I/O table.
4.2.3.1.1	STATE_VECTOR_PREDICT_TASK	New section which has assumed the old section number of RK_GILL.
4.2.3.1.2	Equations of Motion	Section moved to section number 4.3.2.
		Changes made to I/O table.
4.2.3.1.3	Conic Solution	Section moved to section number 4.2.5.2.1.
4.2.3.1.4	Acceleration Models	Section moved to section number 4.2.4.1.1.
		Changes made to I/O table.

TABLE 1.3.- ONORBIT/RENDEZVOUS CHANGE LOG

Section	Section title	Description of change
4.2.3.1.4.1	Altitude Above the Reference Ellipsoid	Section moved to section number 4.2.4.1.1.1.
4.2.3.1.4.2	Earth Relative Velocity Computation	Section moved to section number 4.2.4.1.1.2.
4.2.3.2	Powered Flight Propagation	Section moved to section number 4.2.4.1. Section title changed to Position and Velocity Propagation. Logic made into a subroutine instead of a code since it is executed for both the Orbiter and target vehicles. Changes made to I/O table.
4.2.4	Unmodeled Acceleration State and Covariance Matrix Propagation	Section moved to section number 4.2.5. Changes made to I/O table.
4.2.4.1	Unmodeled Acceleration Bias and Covariance Initialization	Section moved to section number 4.2.5.1.
4.2.4.2	Position-Velocity Submatrix of the State Transition Matrix	Section moved to section number 4.2.5.2.
4.2.5	State and Covariance Matrix Updates	Section moved to section number 4.2.2
4.2.5.1	Auto Inflight Updates	Section moved to section number 4.2.3.1. Interface established to schedule the STATE_VECTOR_PREDICT_TASK as needed rather than making an in-line call to the predictor.

TABLE 1.3.- ORBIT/RENDEZVOUS CHANGE LOG

Section	Section title	Description of change
		Significant changes made to interface with the state vector predict task.
		Local flag, SV_UPDATE, created for use in determining when to call the covariance matrix initialization module.
		Changes made to the I/O table.
4.2.5.2	REL_MAV Display Updates	Section moved to section number 4.2.3.2.
		Changes made to the I/O table.
		New section.
4.2.5.2.1	Conic Solution	Changes made to the I/O table.
4.2.8.1.1	Measurement Interpolation	Changes made to the I/O table.
4.2.8.1.2	Kalman Filter Updates	Changes made to the I/O table.
4.2.8.3.1	Angle Measurements	Equations changed to account for S.T. SOP angles being output in radians, not degrees.
4.3	Orbit Precision State Prediction Principal Function	Added 2 new sections -- RK_GILL and PINES.
		Iterative prediction process modified to iterate on time, not number of steps.
		Changes made to principal function I/O table and to ORBIT_PREDICT I/O table.
4.3.1	Integration of the Equations of Motion	New section number for an existing module.
4.3.2	Equations of Motion	New section number for an existing module.
4.5	User Parameter Processing Principal Function	Change made to interrogate the DOING_REND_MAV flag (set by the sequencer) to determine when to exercise rendezvous functions.

TABLE 1.3.- ORBIT/RENDEZVOUS CHANGE LOG

Section	Section title	Description of change
		Interface established with the INH_ALIGN_DISPLAY to access crew-input INH threshold.
		Logic added to enable the UPP to make its own acceleration threshold test to determine when to use INH data to propagate the Orbiter position and velocity.
		The PWRD_FLI_MAV flag was added as an input for determining when to interrogate the INH data.
		Changes made to the principal function I/O table.
4.5.1	User Parameter State Propagation	Test on the PWRD_FLI_MAV flag added to determine whether or not to look at the INH data.
		Orbiter acceleration threshold test added to determine whether or not to use the INH data in propagating the Orbiter position and velocity.
		Renendezvous phase test modified to interrogate the DOING_REND_MAV flag rather than the REND_MAV_FLAG.
		Changes made to the I/O table.
4.5.1.1	Integration	Calling argument changed in calls to ACCEL_ORBIT.
		Changes made to the I/O table.
4.5.2	Orbit User Parameter Calculations	Renendezvous phase test modified to interrogate the DOING_REND_MAV flag rather than the REND_MAV_FLAG. Appropriate changes made to I/O table.
4.6	Landing Site Update Principal Function	Updated text and tables per CR 193729.
	Appendix	Changes made corresponding to the changes in the text.

TABLE 4.3-3.- PREDICTION SUGGESTED FLAG SETTINGS

Vehicle	Prediction type	GROUP	GROUP	IMP	VNP	ATNP	PRED_STEP	Comments
Orbiter	Precision	4	4	1	0	1	User selects	Full fourth degree potential model. Drag with constant drag coefficient, area.
Orbiter	Rapid precision	2	0	1	0	1	User selects	J ₂ only potential model with constant drag coefficient, area.
Orbiter	Rapid two-body	0	0	0	0	0	0	Single-step two-body P and G series solution.
Target	Precision	4	4	1	0	2	User selects	Full fourth degree potential model drag with constant area, drag coefficient.
Target	Rapid precision	2	0	1	0	2	User selects	J ₂ only potential model with constant drag coefficient, area.
Target	Rapid two-body	0	0	0	0	0	0	single-step two-body P and G series solution.

When prediction is being performed for both vehicles (Orbiter and Target), the same degree and order potential model should be used for each prediction so that potential model errors will be avoided.

3.0 OVERVIEW

3.1 OPERATIONAL NAVIGATION PROGRAM

For the Orbiter flight tests, the requirements for each Operational Navigation Program (ONP) are specified at three levels: system level (A), functional level (B), and detailed level (C). In addition, the Level B and C requirements are specified in separate documents for guidance, navigation, and control (GN&C); system management (SM); vehicle utility (VU) and payloads (PL). This document is the Onorbit and Rendezvous navigation part of the GN&C Level C OFT ONP requirements.

3.2 GN&C SOFTWARE MAJOR FUNCTIONS

The Orbiter general-purpose computer (GPC) provides the following GN&C major functions:

- Guidance (GUID)
- Navigation (NAV)
- Flight Control (FC)
- Redundancy management/moding, sequencing, and control (RM/MSC)
- Subsystem operation programs (SOP)
- Displays and controls (D&C)
- Other

This document specifies the software functional requirements for the GN&C major function, onorbit and rendezvous navigation.

3.3 NAVIGATION SYSTEM OVERVIEW

The basic function of the navigation system is to provide an accurate estimate of the Orbiter and target state using orbital dynamics (for coasting flight), IMU data (for powered flight) and NAVAID data which may be used with or without IMU data. This document provides detailed navigation software requirements for the onorbit operational sequences:

- Onorbit Operational Sequence (OPS 2)
- Flight Control System Checkout Operational Sequence (OPS 8)

3.3.1 Navigation Functions

In general, the navigation software requirements can be divided into the following major functions:

Navigation Control. Performs the initialization of navigation function parameters and sets up the sequencing of functions to accomplish navigation requirements.

Measurement Scheduler. Selects the appropriate sensor measurements in accordance with selection criteria.

Data Handler. Prepares data for sensor measurement processing.

Navigation Reconfiguration. Initializes state vector and covariance matrix for sensor measurement processing, for manual updates, for ground updates or for changes in sensor type.

State and Covariance Propagation. Propagates the state and the covariance matrix for sensor measurement processing. Also propagates state for user parameter calculations.

State and Covariance Update. Determines and performs the state and the covariance matrix updates.

User Parameter Processing. Computes state-related parameters for guidance and display and control, and provides high rate propagation of the state vector.

In this document, the details of the major functions are presented under the following Level B principal functions:

- (1) Onorbit/Rendezvous Navigation Sequencer
- (2) Onorbit/Rendezvous Navigation
- (3) Onorbit User Parameter Processing Sequencer
- (4) Onorbit User Parameter Processing

The details of each function are shown in Appendices B, C, D and F in the form of flowcharts of the modules comprising each function. The interconnection of the functions and component modules is shown by means of a 'block' diagram in Appendix G.

The navigation software requirements as presented make assumptions about how non-navigation functions will be performed. Completion of the software requirements will require adequate definition of the timing and data time-tagging mechanization and the IOP mechanization. Changes in the navigation software requirements may be necessary, depending on actual implementation of the non-navigation functions.

3.3.2 Navigation-Related Functions

The navigation-related function is the Landing Site Update principal function. This function provides the capability to reconfigure the dynamic parameters pertaining to the runway and TACAN sites, which are to carry over into OPS 3. The Landing Site Update function is itself a Level B principal function. Flowcharts for this function are given in Appendix E.

3.3.3 General Requirements

This section discusses software requirements in the categories of service, single-use, or multiple-use that are not uniquely related to the navigation function.

The general requirements include, but are not limited to the following: Coordinate transformations (this publication contains transformations required for navigation).

Onorbit Prediction - this function provides the capability to propagate a state vector forward or backward in time over possibly large time intervals when requested by a user. Onorbit prediction is a Level B principal function.

Flowcharts for the general requirements functions are contained in Appendix C.

3.3.4 Requirements and Assumptions Overview

The following two sections present an overview of the requirements and assumptions of the OFT Onorbit/Rendezvous GN&C navigation-related software.

3.3.4.1 Requirements Overview

The following statements are navigation requirements that must not be violated. To illustrate the requirements, references are made to the flowcharts in Appendix B.

1. During the time that a state vector is being read by non-navigation application software, that state vector or portions thereof will not be updated by the navigation software. The reset equations in the user parameter propagator shall be so protected.
2. Statements that snap data upon entry into navigation shall be made so that a timewise consistent set of data is obtained before the set of data is used.
3. The navigation sensor read functions must not be interrupted by other programs until they are completed.
4. Since the acceleration models are to be used by both a navigation processing principal function (onorbit or rendezvous navigation) and the predictor principal function, execution of the model (for a given cycle) shall not be interrupted (ACCEL_ONORBIT).
5. The specific display interface flags (PWRD_FLT_NAV, REND_NAV_FLAG, MEAS_ENABLE, ANGLES_AIF, RANGE_AIF, RDOT_AIF) shall not have their values changed by any source external to navigation during the execution of a navigation cycle.
6. The Onorbit/Rendezvous sequencer principal function shall have the capability to execute at a maximum rate of one cycle each 1.92 seconds.
7. During any navigation phase, execution of the Onorbit/Rendezvous Sequencer and the Onorbit/Rendezvous Navigation principal function shall take precedence over the execution of the Onorbit Precision State Prediction principal function. This requirement is needed to assure that both the sequencer and navigation principal function executions will not be delayed by execution of the predictor principal function. This requirement shall not apply to the initialization procedures which take place upon entering OPS 2 or OPS 8.

3.3.4.2 Assumptions Overview

The following sections present the assumptions that were used in the development of the Level C Onorbit/Rendezvous requirements. The first section consists of those assumptions made that affect onorbit requirements as well as assumptions

that affect both onorbit and rendezvous requirements. Section 3.3.4.2.2 contains only rendezvous related assumptions.

3.3.4.2.1 Onorbit/rendezvous assumptions

1. Upon entering OPS 2 or OPS 8 the Orbiter position and velocity vectors, obtained from the previous OPS, must be predicted to current time. Since this prediction is essential to the navigation task, the sequencer principal function execution must be dependent on the successful prediction of the Orbiter state vectors. In order to minimize the delay due to the execution of the predictor principal function, the initial step size (PRED_STEP_OPS_INIT), is set to ensure that only one prediction step will be taken by the predictor.
2. No onboard external data are processed during the non-rendezvous portion of operational sequence (OPS) 2 (i.e., onorbit coast and onorbit powered flight). One-way Doppler tracking and data relay satellite system (TDRSS) measurement incorporation is not currently planned for the orbital flight test (OFT) program.
3. A six-dimensional state vector is maintained during nonrendezvous portions of OPS 2 and during OPS 8 (three position and three velocity).
4. Prestored values for a nominal body contact force (due to venting and/or uncoupled thrusting, etc.) and vehicle/payload area configuration are required for acceleration models.
5. The inertial measurement unit subsystem operating program (IMU SOF) provides an estimate of the total accumulated IMU velocity at the time of a data snap in the presence of commfaults.
6. OPS 2 and OPS 8 computational accuracy is assumed to be of AP101 double precision accuracy where mixed mode arithmetic is employed.
7. Incorporation of sensed velocity into the state propagation integrator is controlled by setting the PWRD_FLT_NAV flag in conjunction with an acceleration threshold. This flag is set by either moding, sequencing, and control (MSC), or by the crew via item entry on the REL_NAV display (in OPS 2) or the FCS_DIS_C/O display (OPS 8). MSC will activate the PWRD_FLT_NAV flag upon entrance into Major Mode 202 and deactivate it upon transition from Major Mode 202 to Major Mode 201. The crew can activate/deactivate the PWRD_FLT_NAV flag in Major Mode 201 specifically to handle major manual translation maneuvers and auxiliary power unit (APU) venting (during OPS 8) using the REL_NAV display (OPS 2) or the FCS DIS C/O display (OPS 8).
8. Use of sensed velocity in the navigation state propagator is triggered by entrance into the onorbit or rendezvous powered flight navigation phase (Event 67 OPS 2, or via crew control on the REL_NAV or FCS_DIS_C/O display in Major Mode 201 or 801) and by testing accelerometer output versus prestored threshold levels. The threshold level, in micro g's, can be changed by crew input

on the IMU ALIGN DISPLAY. The crew inputted threshold level will be preserved during OPS 2 and OPS 8 transitions.

9. Backward and forward integration capability is provided for state prediction and propagation.
10. Current attitude is used for propagation.
11. The precision state prediction function has accuracy comparable to that of the precision state propagation function and has the option of being executed in a faster (but less accurate) conic mode.
12. Acceleration models include both attitude-dependent and constant ballistic coefficient drag, a venting/RCS body contact force, and Earth gravity effects.
13. Only one Orbiter and/or target state vector shall be maintained during all navigation phases in OPS 2 and OPS 8.
14. The acceleration due to lift force is assumed to be negligible in the atmospheric drag acceleration model.
15. An automatic in-flight update capability will be provided by which the ground can uplink either an Orbiter or a target state vector (M50) and associated time tag during any navigation phase (rendezvous or nonrendezvous). The following additional assumptions apply to this capability:
 - a. The ground shall uplink one vehicle state (three position, three velocity, associated time tag, and OPCODE) at a time.
 - b. The onboard software receiving these data (ground uplink high-rate special processing S/W processor) will set the DO_OV_UPLINK or DO_TV_UPLINK flag to ON to specify whether the uplinked data pertains to Orbiter or target, and set up one of the following two variable sets depending on the results of this test:

Orbiter uplink		target uplink
<u>R</u> _GND		<u>R</u> _TV_GND
	or	
<u>V</u> _GND		<u>V</u> _TV_GND
<u>T</u> _GND		<u>T</u> _TV_GND
DO_OV_UPLINK = ON		DO_TV_UPLINK = ON
 - c. The navigation software has the capability of reinitializing the Orbiter and/or target state vectors (and associated covariance matrix during rendezvous) in a single navigation cycle.

- d. If a target vector is uplinked during a nonrendezvous navigation phase, it is stored for eventual use in a rendezvous phase.
- 16. Propagation of Orbiter and target position and velocity vectors will be performed by use of the super-G integration scheme during all navigation phases.
- 17. If the sensor (including IMU) SOP's are not in the same general-purpose computer (GPC) as the navigation filter software, then:
 - a. Data and time tag must be preserved as a pair.
 - b. ICC transmission rate must be fast enough such that the data time tag and current time (in navigation GPC) difference shall not adversely affect navigation software performance.

If the sensor SOP's and navigation filter reside in the same GPC, then:

- a. Data must be time tagged.
- b. Data must be the latest available at the time of the data snap.
- 18. The onorbit/rendezvous navigation sequencer will always snap IMU data and predict the last available state vector to current time when a memory transition has been performed:

- OPS 1 to 2
- OPS 2 to 8
- OPS 3 to 2
- OPS 8 to 2
- OPS 0 to 2

- 19. The onorbit/rendezvous navigation sequencer is capable of responding to the following crew-controlled functions on the REL_NAV and FCS_DIS_C/O displays:
 - a. REL_NAV
 - (1) Enable/disable onorbit and rendezvous navigation phases.
 - (2) Set flags for powered flight and coasting flight during Major Mode 201 (refer to Assumption 6).
 - (3) Allow measurement processing during rendezvous navigation, Major Mode 202.
 - b. FCS_DIS_C/O display (OPS 8): Set positive feedback flags to display for indicating powered flight or coasting flight conditions.

3.3.4.2.2 Rendezvous-only assumptions

1. Entrance into the rendezvous navigation phase shall require target position and velocity vectors that have successfully been predicted to within a design dependent tolerance of current navigation time. A flag, DOING_REND_NAV, shall be set to indicate to the crew as well as other software that the rendezvous navigation phase is active.
2. The onboard navigation software will store premission data for only one target vehicle.
3. It is assumed that one of the vehicles (either target or Shuttle) will have an accurately known position and velocity vector throughout the rendezvous navigation phase. The onboard navigation will carry a flag (SHUTTLE_FILTER_FLAG) which will determine whether the Shuttle or target state vector will be updated by the Kalman filter. The present design assumes that the SHUTTLE_FILTER_FLAG will be a mission dependent (I-LOAD) parameter; however, it is anticipated that future requirements may dictate that this flag be changed via UPLINK or crew display. Accordingly, any implementation should have the flexibility to allow for such a change with minimum impact.
4. The state vector maintained for rendezvous navigation will consist of 13 components.

<u>Component no.</u>	<u>Description</u>
1-3	Vehicle position (Shuttle or target)
4-6	Vehicle velocity (Shuttle or target)
7-9	Unmodeled acceleration estimates
10-13	Rendezvous tracker bias estimates

5. A capability shall be available to make the unmodeled acceleration states consider parameters only. In this mode, the unmodeled acceleration states are not updated by Kalman processing but the statistics are carried in the covariance matrix to act as state noise. An I-LOAD parameter will determine if this capability is in operation or not and this parameter will not be changed throughout the mission.
6. There is no capability to uplink vents or thrusts for the target vehicle.
7. A 13 by 13 covariance matrix of Aries mean of 1950 position and velocity, unmodeled acceleration bias errors, and of (at most) four rendezvous tracker (instrument) biases is propagated during rendezvous coast and rendezvous powered flight navigation phases.
8. A valid or appropriate target vector shall always be I-LOADED or UPLINKED prior to entry into the rendezvous navigation phase.
9. Upon entering rendezvous navigation, the covariance matrix is initialized to values stored in certain memory locations. These values are initialized

through I-LOAD and the position-velocity submatrix may be redefined with a ground uplink at any time.

10. The capability to load a premission determined set of known sensor biases (determined by calibration) into the bias slots of the navigated state vector shall be provided.
11. Both target and Orbiter states shall be propagated but only one state will be updated by the Kalman filter.
12. The covariance propagation shall be done at a multiple (MCYCLE) of the state propagation rate to allow for slower measurement processing. The following subfunctions shall be done at the covariance propagation rate.
 - a. Sensor measurement selection
 - b. Measurement reconfiguration
 - c. Covariance matrix propagation
 - d. All measurement incorporation subfunctions
 - e. Measurement processing statistics
13. All rendezvous tracker bias variances are propagated as exponentially correlated random variables in the error covariance matrix propagation.
14. The unmodeled acceleration bias states are propagated as exponentially correlated random variables.
15. The covariance matrix can be reinitialized in any of four ways:
 - a. Execution of Orbiter to target state transfer on the REL_NAV display,
 - b. Execution of target to Orbiter state transfer on the REL_NAV display,
 - c. Execution of covariance matrix reinitialization on the REL_NAV display, or
 - d. Auto inflight update of either the target or the Orbiter.

In each of these cases the covariance matrix is set to the values contained in a specified set of memory locations. The position and velocity portions of the covariance matrix are computed using parameters that can be changed by ground uplink.

16. The following external data will be processed during the rendezvous coast navigation or during rendezvous powered flight when measurement processing is enabled and the acceleration level is below a predetermined threshold.

- a. Rendezvous radar shaft angle, trunnion angle, range, and range rate
 - b. Star tracker horizontal and vertical angles
 - c. Crew optical alinement sight (COAS) horizontal and vertical angles.
17. External measurement angle data are selected and processed mutually exclusively on an instrument basis. The rendezvous radar range and range rate may be processed with COAS, star tracker, or rendezvous radar angles. The display interface processor (DIP) will ensure this by activating the navigation sensor selection ENABLE flag for only the most recently crew-selected instrument.
 18. External measurement data processing is inhibited for display and state vector updates whenever IMU sensed delta velocities are in excess of a design dependent amount (MEAS_THRESHOLD).
 19. During Major Mode 202, when the MEAS_ENABLE switch on the REL_NAV display is set to OFF, the measurement statistics will be computed for display (assuming the data are valid), but the measurements will not be incorporated into the state vector update.
 20. If a sensor AUTO/INHIBIT/FORCE (AIF) flag is switched to FORCE by the crew, this FORCE will be acknowledged by navigation for one navigation cycle only. After one cycle the flag must be reset to FORCE in order to force data. After the AIF flag has been processed, a copy of the AIF flag is communicated to the REL_NAV display by navigation.
 21. There shall be a bilevel edit criterion in the navigation filter. If the crew attempts to force data, the allowable residual ratio threshold shall be formulated as the larger of either the sum of the last residual ratio for the measurement type being processed and a design dependent amount (DELTA_RESID_RATIO) or the number 1. For angle data the last residual ratio is equal to the greater of the two angle residual ratios from the previous cycle.
 22. There shall be a data valid flag for rendezvous radar range and a data valid flag for rendezvous radar range rate. There will be a single data valid flag for each of the following angle sets: Rendezvous radar angles, star tracker angles, and COAS angles.
 23. COAS processing is formulated such that data which is stale by more than a design dependent amount (DELTA_COAS_MAX) is considered invalid data and is not processed. Furthermore, the same data will not be incorporated twice by the filter.
 24. The star tracker SOP shall supply a flag indicating that the star tracker is in the target tracking mode.

If the star tracker is not in the target tracking mode then the angle data are considered invalid and it is not processed by the filter.

25. The Rendezvous Radar SOP shall supply a flag indicating if the rendezvous radar is in the self test mode and, if it is, none of the rendezvous radar measurements (range, range rate, or angles) are processed by the filter.
26. Kalman filter statistics (residuals and residual ratios) will be calculated and displayed for each sensor type (range, range rate, angles) whenever rendezvous navigation is enabled and the sensor data are valid.

3.3.4.2.3 General requirements

1. Figure 3.3-1 presents the assumed verified OFT transitions for OPS 2 and OPS 8 and a summary of the events and major mode (MM) transitions that the Onorbit/Rendezvous Navigation Sequencer principal function must account for. The following list of assumptions applies to these verified transitions:
2. There are four navigation phases: onorbit coast, rendezvous coast, onorbit powered flight, and rendezvous powered flight.
3. OPS 2 can be entered from OPS 1 and can only begin with the onorbit coast navigation phase of the Onorbit/Rendezvous Navigation principal function.
4. A flag, REND_NAV_FLAG, shall be set (and reset) external to the onorbit/ rendezvous navigation sequencer and onorbit/rendezvous navigation principal function. It is assumed that the crew will control this flag setting via the REL NAV display. MSC may also control the flag for automatic transitions.
5. Once the onorbit navigation phase or the rendezvous navigation phase has been activated (while in Major Mode 201), the transition from one to the other can be controlled via crew resetting of the REND_NAV_FLAG via the REL NAV display. This option is also available during Major Mode 202.
6. Entry into OPS 2 from OPS 3 can only occur when onorbit navigation is used (i.e., cannot begin OPS 2 with rendezvous navigation when coming from OPS 3).
7. Whenever reentering OPS 2 from OPS 00, entry is assumed to be made into Major Mode 201 with onorbit navigation active.
8. Transition to OPS 3 from OPS 2 (Major Mode 201) can occur while either onorbit or rendezvous navigation is active.
9. Transitions into OPS 2 and OPS 8 can only begin with onorbit navigation active in the coast flight phase.
10. It is assumed that OPS 2 and OPS 8 are separate memory loads in which all navigation software for the latter is contained within the former. A memory transition shall take place to transfer those OPS 2 principal functions needed for OPS 8, namely

- a. Onorbit/Rendezvous Navigation Sequencer
- b. Onorbit/Rendezvous Navigation
- c. Onorbit/Rendezvous User Parameter Processing Sequencer
- d. Onorbit User Parameter Processing
- e. Onorbit Predictor

The navigation sequencer will currently indicate a cancellation and rescheduling of ONORBIT_RENDEZVOUS_NAVIGATION during the transition from OPS 8 to OPS 2 or OPS 2 to OPS 8, because of this assumption.

3.4 TRACEABILITY

Table 3.4 shows the traceability of the software segments in FSSR Level C with respect to the CPDS Level B.

TABLE 3.4.- SOFTWARE REQUIREMENT TRACEABILITY

CPDS Level B Section No.	Software Segment	FSSR Level C Section No.
4.148	Onorbit/Rendezvous Navigation Sequencer	4.1
4.198	Onorbit User Parameter Processing Sequencer	4.4
4.126	Onorbit/Rendezvous Navigation	4.2
4.246	Landing Site Update	4.6
4.22	Onorbit User Parameter Processing	4.5
4.224	Onorbit Predictor	4.3

3.5 OPERATIONAL SEQUENCES AND MAJOR MODES

Table 3.5 identifies the OPS 2 and OPS 8 operation sequence major modes as referenced in Section 4, Detailed Requirements, and Appendix B. Detailed descriptions may be found in the Level B CPDS.

TABLE 3.5.- OPERATION SEQUENCE MAJOR MODES

Major Mode No.	Onorbit/Rendezvous Phases
201	Onorbit powered flight Onorbit coast Rendezvous powered flight Rendezvous coast
202	Onorbit powered flight Rendezvous powered flight
OPS 8	Onorbit powered flight Onorbit coast

3.6 IMPLEMENTATION CONSTRAINTS

The navigation subsystem design is capable of recovering from the effects of many transient-type errors. Accordingly, the software design shall not preclude this capability by causing a program halt, permanent discontinuance of navigation processing, or loss of protected data as a result of program check or error interrupts.

Check or error interrupts shall be prevented by software safeguards, or standard fixup and error returns shall be provided which are appropriate in the navigation function as described below.

1. Floating Point Overflow. The operation in process should be terminated and the previous stored value of the variable retained.
2. Floating Point Underflow. This may be treated in the same manner as floating point overflow, or the variable may be set to zero and processing continued.
3. Divide by Zero. This should be treated in the same manner as floating point overflow.
4. Square Root. The square root of a negative number should be treated in the same manner as floating point overflow.
5. Arc Sine. If the argument is greater than +1, a value of $\pi/2$ should be returned. If the argument is less than -1, a value of $-\pi/2$ should be returned. In either case, processing shall not be terminated.
6. Arc Cosine. If the argument is greater than +1, a value of zero should be returned. If the argument is less than -1, a value of π should be returned. In either case, processing shall not be terminated.
7. Arc Tangent. If both arguments are zero, a value of zero should be returned.
8. Logarithm. If the argument of the logarithm function is negative or zero, the operation in process should be terminated, and the previous value of the result retained.
9. Sine and Cosine. The returned value of sine and cosine functions should be limited to the interval $(-1,1)$ and the functions shall be capable of accepting any valid floating point numbers as arguments.

4.0 DETAILED REQUIREMENTS

The various subsections of this section specify the detailed requirements for the Shuttle navigation system flight software package. This document contains orbital flight test (OFT) detailed requirements for Navigation and User Parameter Processing principal functions for the orbit operations computer load (on orbit and rendezvous), Operational Sequence (OPS) 2. In addition, requirements dealing with other navigation software functions during OPS 8 and OPS 00 are also addressed.

When viewed in the larger context of the total Shuttle flight software, the navigation software package documented herein is a modular system whose function is to supply various parameters required by other major modular systems, such as guidance, displays, flight control, etc. The requirements placed upon the navigation system by these various users often play a large role in determining the design structure and cyclic rate structure of the navigation system. The required interfaces between the navigation system and the other major software systems that use navigation system data are presented in the Level B CPDS document that controls all the interfaces between principal functions.

4.1 ONORBIT/RENDEZVOUS NAVIGATION SEQUENCER PRINCIPAL FUNCTION

The Onorbit/Rendezvous Navigation Sequencer principal function must initialize and sequence the Onorbit/Rendezvous navigation principal function during OPS 2 while the following major modes are active:

Major Mode 201 - Onorbit coast

Major Mode 202 - Maneuver execute

The Onorbit/Rendezvous Navigation Sequencer principal function must also initialize and sequence the Onorbit/Rendezvous Navigation principal function OPS 8 (orbital operation checkout).

The Onorbit/Rendezvous Navigation Sequencer principal function must also interface with certain crew controls on the REL NAV and FDS DIS C/O displays relating to selection of rendezvous navigation (REND_NAV_FLAG), to selection of powered flight versus coasting flight navigation phases, and to selection of measurement processing in Major Mode 202 when in rendezvous navigation.

Detailed requirements for Onorbit/Rendezvous Navigation processing principal function are identified in the specific principal function description section 4.2. Cues (events) for performing the proper navigation initialization and sequencing during OPS 2 and OPS 8 are defined in the Level B GN&C CPDS. The particular events and resulting navigation software actions pertaining to the Onorbit/Rendezvous Navigation Sequencer principal function are shown in table 4.1-1. Dynamic parameter input/output data flow between the Onorbit/Rendezvous Navigation Sequencer principal function and other principal functions are shown in table 4.1-2.

TABLE 4.1-1.- ONORBIT/RENDEZVOUS NAVIGATION SEQUENCER EVENTS

Event no.	Description	Navigation Criteria	Navigation Action
THE FOLLOWING PERTAIN TO SEQUENCER FUNCTIONS DURING OPS 2.			
Begin coasting flight navigation phases (onorbit or rendezvous).			
60	Transition from OPS 1 to MM201 (begin OPS 2)	OPS 201 PRO	Entering into an onorbit coast navigation phase: SET: CURR_ORB_MASS = WT_DISP/G_2_FPS2 NAV_CURR_ORB_MASS = CURR_ORB_MASS CALL: OPS_2_OR_8_INITIALIZE SCHEDULE: NAV_ONORBIT_RENDEZVOUS, repeat every: DT_NAV_STATE_PROP
60A	Transition from OPS 8 to MM201 (begin OPS 2)		The REND-NAV-FLAG is assumed to be in the OFF state for this event: Same action as EVENT_60 except current Orbiter mass is calculated as: CURR_ORB_MASS=MASS_INIT

4.1.1 Sequencing Operations and Major Mode Transitions (ONORBIT, REND, NAV, SEQUENCER)

The Onorbit/Rendezvous Navigation Sequencer principal function performs specific actions which control the execution of the Onorbit/Rendezvous Navigation principal function based on navigation phase and major mode transitions. These tasks are performed by the Sequencing Operations and Major Mode Transitions subfunction and include the following tasks for OPS 2 control:

- response to events for entering OPS 2
- response to events for exiting OPS 2
- response to events for major mode transitions within OPS 2
- response to crew entry on the REL NAV DISPLAY regarding selection of powered flight phase (both onorbit and rendezvous)
- response to crew entry (REL NAV DISPLAY) regarding selection of onorbit or rendezvous navigation phase (powered or coasting flight)

For OPS 8 control the following tasks are performed:

- response to events for entering OPS 8
- response to events for exiting OPS 8
- response to crew entry on the FCS/DED DISP C/O DISPLAY regarding selection of powered flight phase

The events for OPS 2 and OPS 8 navigation control are summarized below. Detailed requirements are specified separately below for OPS 2 and OPS 8.

- Events to enter OPS-2
 - 60 OPS-1 → OPS-2
 - 60A OPS-8 → OPS-2
 - E1 OPS-3 → OPS-2
 - 84 OPS-00 → OPS-2
- Events to exit OPS-2
 - 60B OPS-2 → OPS-8
 - 83 OPS-2 → OPS-00
 - 85 OPS-2 → OPS-3
- Events to enter OPS-8
 - 60B OPS-2 → OPS-8

- Events to exit OPS-8
 - 60A OPS-8 → OPS-2
 - 60H OPS-8 → OPS-3
- Events during OPS-2 & 8
 - 73 MM202 → 201
 - 67 MM201 → 202

A. Detailed requirements.

Part I.- OPS 2 Requirements

The detailed sequencing and major mode transition requirements for the OPS 2 portion of the Onorbit/Rendezvous Navigation Sequencer principal function are described as follows:

1. If an onorbit coast navigation phase is begun by entry into Major Mode 201 from OPS 1, OPS 3, OPS 8 or OPS 00 (EVENTS E1, 60, 60A, or 84), the Onorbit/Rendezvous Navigation Sequencer principal function shall provide the capability to initialize the Orbiter state vector, mass, and other required navigation parameters on the basis of prestored computer locations unaffected by the computer program memory load reconfiguration. The following sequence should be followed:
 - a. Compute the value for Orbiter mass as follows:

If OPS 2 is to be entered from OPS 1 or OPS 3 the Orbiter mass shall be calculated as:

$$\text{CURR_ORB_MASS} = \text{WT_DISP/G_2_FPS2} \quad \text{F3}$$

Otherwise, Orbiter mass shall be reset to a saved value:

$$\text{CURR_ORB_MASS} = \text{MASS_INIT}$$
 - b. Store the computed mass value into a NAV slot for use by navigation.

$$\text{NAV_CURR_ORB_MASS} = \text{CURR_ORB_MASS}$$
 - c. An initialization operation shall now be performed to obtain current IMU data, predict the last saved OPS sequence Orbiter position and velocity vectors to current time, reset parameters for user parameter state propagation, and initialize flags to OPS 2 or OPS 8 initial values (refer to section 4.1.2.1 for detailed requirements):

F3 This equation shall be protected against division by zero (reference 3.6-3).

CALL: OPS_2_OR_8_INITIALIZE

- d. After completion of initialization, the capability shall be provided for sequencing the Onorbit/Rendezvous Navigation principal function at the designated repetition rate, DT_NAV_STATE_PROP.
2. If OPS 2 is not being entered, tests for detecting leaving OPS 2 to go to OPS 8 (EVENT 60B), OPS 00 (EVENT 83), or OPS 3 (EVENT 85) are made. If any of these 3 transitions is detected,

CALL: NAV_EXIT

(section 4.1.1.2) to store the necessary information into protected locations for the new OPS sequence.

3. If transitions into or out of OPS 2 have not been detected, tests for transitions in major mode in OPS 2 are made.
 - a. The test for transition from MM202 to MM201 (EVENT_73) is made. If EVENT_73 is ON, the powered flight flag, MM202 measurement enable flag, and the measurement enable positive feedback flag (for REL_NAV_DISPLAY) must be set to OFF.

PWRD_FLT_NAV = OFF

MEAS_ENABLE = OFF

DOING_MEAS_ENABLE = OFF

- b. If EVENT 73 is OFF, the test for transition from MM201 to MM202 (EVENT 67) is made. If EVENT_67 is ON, the powered flight flag is set to ON.

PWRD_FLT_NAV = ON

In any event, the positive feedback flag for powered flight is set for the REL NAV display to the value of the powered flight navigation flag.

DOING_PWRD_FLT_NAV = PWRD_FLT_NAV

4. A test is made to detect the following:
 - A transition into or out of the rendezvous navigation phase, or
 - the rendezvous navigation initialization target prediction task has been initiated but not completed.
 - a. If $REND_NAV_FLAG \neq REND_NAV_FLAG_LAST$, a transition has occurred; or if $REND_NAV_INIT_PRED = ON$, then the target prediction task has not been completed. Thus the $REND_NAV_FLAG$ and $REND_NAV_INIT_FLAG$ are interrogated to determine the nature of the transition and the state of the target prediction.

- (1) If `REND_NAV_FLAG = ON` or `REND_NAV_INIT_PRED = ON` then the rendezvous navigation initialization subfunction is invoked

CALL: `REND_NAV_INIT`

(See section 4.1.2.2)

- (2) If `REND_NAV_FLAG = OFF` and `REND_NAV_INIT_PRED = OFF`, the rendezvous navigation phase will be exited.

CALL: `REND_NAV_EXIT`

(See section 4.1.1.1)

- b. If `REND_NAV_FLAG = REND_NAV_FLAG_LAST` and `REND_NAV_INIT_PRED = OFF`, then a transition has not occurred; and the rendezvous navigation initialization prediction task is not in progress. Thus the sequencer control logic has been completed for this navigation cycle.

Part II.- OPS 8 Requirements:

The detailed sequencing and major mode transition requirements for the OPS 8 portion of the Onorbit/Rendezvous Navigation Sequencer principal function are described as follows:

1. If the onorbit coast navigation phase is begun by entry into GN&C OPS 8 from OPS 2 (Event 60B), the Onorbit/Rendezvous Navigation Sequencer principal function shall provide the capability to initialize the Orbiter state vector and other required navigation parameters on the basis of prestored data and OPS 2 data obtained from protected computer locations unaffected by the computer program memory load reconfiguration. A flag, `REND_NAV_FLAG`, will be maintained in the OFF state (by MSC) throughout OPS 8 as rendezvous navigation phase is not available in this OPS sequence. This following initialization sequence shall be performed:

- a. Initialize the current Orbiter mass as saved from OPS 2:

`NAV_CURR_ORB_MASS = MASS_INIT`

- b. Perform an initialization operation to obtain current IMU data, predict the last saved OPS sequence Orbiter position and velocity vectors to current time, reset parameters for user parameter state propagation, and initialize flags to OPS 2 or OPS 8 initial values (refer to section 4.1.2.1 for detailed requirements):

CALL: `OPS_2_OR_8_INITIALIZE`

- c. After completion of this initialization, the capability shall be provided for sequencing the Onorbit/Rendezvous Navigation principal function at the designated repetition rate (DT_NAV_STATE_PROP) during OPS 8.
2. If a transition for entering OPS 8 was not detected, tests are made to detect leaving OPS 8 to enter OPS 2 (EVENT 60A) or OPS 3 (EVENT 60H). If either event is "ON",

CALL: NAV_EXIT

to store necessary information into protected locations for the next OPS sequence.

3. If transitions into and out of OPS 8 have not been detected, the positive feedback flag for powered flight navigation is set (for the FCS/DED DISP C/O DISPLAY) to the value of the powered flight navigation flag.

DOING_PWRD_FLT_NAV = PWRD_FLT_NAV

- B. Interface Requirements. Input and output parameters are given in Table 4.1.1.
- C. Processing Requirements. None
- D. Constraints. The following additional constraints apply to the requirements presented in Section A:

1. The following flags are set by either REL_NAV (via crew input) or FCS/DED DISP C/O DISPLAY (crew input):

REND_NAV_FLAG

PWRD_FLT_NAV

MEAS_ENABLE

and should not be changed (in value) by these external functions during any given cycle of the Onorbit/Rendezvous Navigation principal function during any navigation phase since a timewise consistent set of navigation data is required (i.e., a completion of a navigation cycle) to perform the various navigation functions.

2. Memory transitions shall only be performed following the completion of a navigation cycle.
3. The maximum repetition rate for the Onorbit/Rendezvous Navigation Sequencer principal function shall be 1.92 seconds.

- E. Supplemental Information. A suggested implementation of these requirements is illustrated in the Appendix B flow diagrams:

**See initialization parameters, section 4.7

4.1.1.1 Rendezvous Navigation Phase Termination (REND_NAV_EXIT)

The purpose of the rendezvous navigation phase termination subfunction is to perform the necessary operations required when a rendezvous navigation phase is terminated in preparation for a transition to an onorbit navigation phase. This action occurs during OPS 2 when the crew or MSC changes the value of the REND_NAV_FLAG from a value of ON to OFF (crew control of the REND_NAV_FLAG is via the REL_NAV display control, RNDZ_NAV_ENA). This subfunction is invoked by the sequencing operations and major mode transitions subfunction (section 4.1.1, ONORBIT_REND_NAV_SEQUENCER).

- A. Detailed Requirements. When called, this subfunction shall first set the unmodeled acceleration biases to zero. These bias terms were solved for by the rendezvous navigation filter and need to be set to zero for non-rendezvous navigation phases.

UNMOD_ACC_BIAS = 0.

The display parameters initialization subfunction shall now be executed to zero the ACCEPT/REJECT counters for display and measurement processing requirements:

CALL: DISPLAY_COUNT_INIT

Detailed requirements for the above subfunction are stated in section 4.1.2.2.1.2.

The "last" flag is turned OFF to indicate the rendezvous navigation is no longer active.

REND_NAV_FLAG_LAST = OFF

The positive feedback flag for the Rel Nav Display is set to OFF to indicate that rendezvous navigation is no longer active.

DOING_REND_NAV = OFF

- B. Interface Requirements. Input and output parameters for this subfunction may be found in table 4.1.1.1.
- C. Processing Requirements. This subfunction shall be called by the sequencing operations and major mode transitions subfunction (ONORBIT_REND_NAV_SEQUENCER) when it is required to transition from rendezvous to onorbit navigation phases during OPS 2.
- D. Constraints. None
- E. Supplemental Information. A suggested implementation of this subfunction may be found in Appendix B flow diagrams:

REND_NAV_EXIT

4.1.1.2 Operation Sequencer Termination (NAV_EXIT)

Specific actions are required by the onboard navigation software when either the OPS-2 or OPS-8 operational sequence is terminated in preparation for transition to another OPS sequence. These actions are primarily concerned with protecting special memory locations to preserve data required for the next OPS sequence.

- A. Detailed Requirements. The Operations Sequence Termination subfunction shall provide the capability to save off (in protected memory locations) certain navigation-related data sets for transmission across a memory transition from one operational sequence to another and, once the data has been saved, terminate the Onorbit/Rendezvous Navigation principal function. This subfunction shall perform these functions for the termination of OPS-2 and OPS-8 as follows:

1. If OPS-2 or OPS-8 is being terminated for a transition to either OPS-8 (from OPS-2, Event 60B), or to OPS-2 (from OPS-8, Event 60A), or to OPS-00 (from OPS-2, Event 83) the current Orbiter mass must be saved prior to termination:

MASS_INIT = CURR_ORB_MASS

2. In all cases where OPS-2 or OPS-8 is terminated, the following parameters shall be saved off prior to termination:

R_FILT_INIT = R_FILT

V_FILT_INIT = V_FILT

T_FILT_INIT = T_LAST_FILT

Although the variable names with the _INIT have been designated as unique variables, this may not be required if the same physical core location can be used for R_FILT (for example) in each memory load. The _INIT notation has been used for visibility purposes only.

3. During OPS-2 and OPS-8 once the above data have been stored, execution of the Onorbit/Rendezvous Navigation principal function shall be cancelled.

CANCEL: NAV_ONORBIT_RENDEZVOUS

- B. Interface Requirements. Input and output requirements for this subfunction are defined in table 4.1.1.2.

- C. Processing Requirements. This subfunction is called by the following subfunction:

ONORBIT_REND_NAV_SEQUENCER (section 4.1.1)

- D. Constraints. None

- E. Suggested Implementation. A suggested implementation in the form of a detailed flowchart may be found in Appendix B under the name NAV_EXIT.

TABLE 4.1.1.2 NAV_EXIT INPUT/OUTPUT

T_FILT_INIT		*

*See principal function I/O table for ONORBIT_REND_NAV_SEQUENCER.

4.1.2 Operation Sequence Initialization (OPS_2_OR_8_INITIALIZE)

The purpose of the operation sequence initialization subfunction is to perform specific functions required when either operations sequence 2 (OPS 2) or 8 (OPS 8) is entered from another OPS sequence (i.e., OPS 1, OPS 3, OPS 00, OPS 2 or OPS 8).

A. Detailed Requirements.

1. Snap current accumulated inertial measurement unit (IMU)-sensed velocity data and associated time tag (section 4.2.2.1), SNAP (V_CURRENT_FILT, T_CURRENT_FILT) and immediately store the snapped IMU and time data in local variable locations.

V_LAST_FILT = V_CURRENT_FILT

T_LAST_FILT = T_CURRENT_FILT

2. Initialize the unmodeled acceleration biases solved for in the filter to zero. These bias terms are solved for by the rendezvous navigation filter and need to be zeroed for non-rendezvous navigation phases:

UNMOD_ACC_BIAS = 0.

- Compute the square root of MU of the Earth for the precise predictor and precision state propagation:

SQR_EMU = SQRT(EARTH_MU)

3. Set up the proper parameters to predict the stored Orbiter state vector to current time (refer to section 4.3 for predictor requirements; the following are unique COMPOOL locations for use by the predictor):

PRED_ORB_AREA = REF_ORB_AREA

PRED_ORB_MASS = NAV_CURR_ORB_MASS

PRED_ORB_CD = REF_ORB_CD

GMDP = GM_DEG

GMOP = GM_ORD

DMP = DFL

VMP = VFLOV_PRED

ATMP = 1

PRED_STEP = PRED_STEP_OPS_INIT

T_PRED_INIT = T_FILT_INIT

R_PRED_INIT = R_FILT_INIT

V_PRED_INIT = V_FILT_INIT

T_PRED_FINAL = T_LAST_FILT

Then call the onorbit precise prediction principal function

CALL: ONORBIT_PREDICT

4. Finally, reset the following onorbit navigation parameters:

R_FILT = R_PRED_FINAL

V_FILT = V_PRED_FINAL

5. Initialize those parameters required by the user parameter state propagation subfunction (section 4.5.1) through the use of the Orbiter state vector reset task (section 4.1.2.1) for the Orbiter vehicle only:

CALL: SHUTTLE_RESET

6. Set a flag that indicates use of the coasting flight state propagation algorithm.

PWRD_FLT_NAV = OFF

7. Signal that the proper initialization has been accomplished to allow the Onorbit/Rendezvous User Parameter Processing Sequencer principal function to begin scheduling.

SET: OPS_2_OR_8_INITIALIZE COMPLETE = ON

- B. Interface Requirements. The input and output requirements for this subfunction are described in table 4.1.2.
- C. Processing Requirements. This subfunction is called by the sequencing operations and major mode transitions subfunction, section 4.1.1; ONORBIT_REND_NAV_SEQUENCER.
- D. Constraints. None
- E. Supplemental Information. A suggested implementation of this module can be found in Appendix B; OPS_2_OR_8_INITIALIZE.

4.1.2.1 Orbiter State Vector Reset (SHUTTLE_RESET)

The purpose of the Orbiter state vector reset subfunction is to provide updated state vector associated parameters to the user parameter state propagation subfunction (section 4.5.1) at the beginning of OPS sequence 2 or OPS 8 and at the end of every navigation cycle through the use of navigated state parameters.

- A. Detailed Requirements. At the completion of each OPS sequence 2 or 8 initialization procedure and at the completion of a navigation cycle, the Orbiter state vector reset subfunction shall be called:

CALL: SHUTTLE_RESET

1. This subfunction shall then initialize the reset Orbiter state vector and associated IMU sensed velocity reading as follows:

R_RESET = R_FILT

V_RESET = V_FILT

V_IMU_RESET = V_LAST_FILT

T_RESET = T_LAST_FILT

2. Additionally, a flag shall be set to indicate to the user parameter state propagation subfunction that a navigated state update has occurred.

FILT_UPDATE = ON

These parameters are required by the user parameter propagator to reinitialize the user parameter state following the completion of each navigation cycle.

- B. Interface Requirements. The input and output requirements for this subfunction are shown in table 4.1.2.1.
- C. Processing Requirements. This subfunction is called by the following modules:

OPS_2_OR_8_INITIALIZE

NAV_ONORBIT_RENDEZVOUS

- D. Constraints. None

- E. Supplemental Information. A suggested implementation of this subfunction can be found in Appendix B in the form of a flow diagram:

4.1.2.2 Rendezvous Navigation Initialization (REND_NAV_INIT)

The Rendezvous Navigation Initialization subfunction is responsible for the proper initialization of selected rendezvous related parameters whenever the Onorbit/Rendezvous Navigation Sequencer principal function has detected the following:

- (a) There is a request to initialize the rendezvous navigation phase, or
- (b) The prediction of the target vehicle has been initiated by the rendezvous navigation initialization subfunction but the prediction has not been completed.

This subfunction shall be responsible for the following tasks.

- Schedule the state vector prediction task in order to predict the target position and velocity vectors to current time.
- Set selected flags to OFF to insure the proper functioning of the Onorbit/Rendezvous Navigation principal function should the rendezvous navigation phase be canceled and then re-entered.
- Set certain parameters for the unmodeled acceleration bias propagation to values used for coasting flight.
- Initialize the covariance matrix.
- Store the current target position and velocity vectors for use by the User Parameter Processing principal function.

A. Detailed Requirements. This subfunction shall perform the following steps in the order indicated:

1. The prediction task indicator flag, PRED_USE, is interrogated for a zero value to determine if the state vector prediction task is available for scheduling. If PRED_USE = 0 then the following parameters are defined preceding the scheduling of the state vector prediction task.

```

REND_NAV_INIT_PRED = ON
PRED_USE = 4
TV_PREDICT_FAIL = OFF
GM DP = GM DEG
GM OP = GM ORD
DMP = DFL
VMP = VFLTV_PRED
ATMP = ATFL_TV
PRED_STEP = PREC_STEP_PRED
R_PRED_INIT = R_TV
V_PRED_INIT = V_TV
T_PRED_INIT = T_TV

```

The state vector prediction task is then scheduled.

SCHEDULE: STATE_VECTOR_PREDICT_TASK

2. If the PRED_USE flag is nonzero, it is tested for a value of 6 which indicates that the state vector prediction task has determined that the prediction interval is too large; hence no prediction will take place.

If PRED_USE = 6 then the following flags are set.

```
PRED_USE = 0
TV_PREDICT_FAIL = ON
REND_NAV_INIT_PRED = OFF
REND_NAV_FLAG = OFF
```

The rendezvous navigation flag is set to OFF so that the rendezvous navigation initialization subfunction will not be invoked again until the REND_NAV_FLAG is reset to ON by the crew.

3. If the PRED_USE flag is not set to 6, then it is tested for a value of 5 which indicates that the state vector prediction task has successfully predicted the target state vectors.

If PRED_USE = 5 then the following actions are taken.

- (a) The predictor outputs are stored, and flags are set to free the predictor for other navigation users.

```
PRED_USE = 0
T_TV = T_PRED_FINAL
R_TV = R_PRED_FINAL
V_TV = V_PRED_FINAL
REND_NAV_INIT_PRED = OFF
```

- (b) Next, the REND_NAV_FLAG is tested for an ON value to determine if the crew request for activating the rendezvous navigation phase is still valid. If the REND_NAV_FLAG is on, the following actions are taken:

- (1) Flags are set to indicate that the unmodeled acceleration bias state statistics are to be initialized to their coast values.

```
NOISY_NAV_MEAS = OFF
COV_PWRD_FLT = OFF
COV_PWRD_FLT_LAST = OFF
```

- (2) Unmodeled acceleration bias state statistical parameters are initialized to their coast values.

```
TAU_UNMOD_ACC_COV = TAU_U_A_COAST
VAR_UNMOD_ACC = VAR_U_A_COAST
COV_ACCEL_UVW_INIT = COV_U_A_COAST
```

- (3) The rendezvous covariance initialization function is called to initialize the covariance matrix as described in section 4.1.2.2.1.

CALL: REND_COV_INIT

- (4) The target state vector reset subfunction resets the user parameter processing state vectors as described in section 4.1.2.2.2.

CALL: TARGET_RESET

- (5) The flags REND_NAV_FLAG_LAST and DOING_REND_NAV are set to ON to indicate that the rendezvous navigation phase is now active.

REND_NAV_FLAG_LAST = ON
DOING_REND_NAV = ON

- B. Interface Requirements. Input and output parameters are specified in table 4.1.2.2.
- C. Processing Requirements. The subfunction is called by ONORBIT_REND_NAV_SEQUENCER (section 4.1.1).
- D. Constraints. None
- E. Supplemental Information. A suggested implementation of these requirements is illustrated in Appendix B with REND_NAV_INIT.

4.1.2.2.1 Covariance matrix initialization (REND_COV_INIT)

The covariance matrix initialization subfunction shall perform the following tasks upon entering the rendezvous phase, whenever there is an automatic inflight update during the rendezvous phase, or whenever the crew requests a covariance matrix reinitialization or a state vector transfer.

1. Initialize the covariance matrix.
 2. Zero the counter (I-CYCLE) for the asynchronous covariance propagation.
 3. Set certain flags to OFF so that the rendezvous sensor initialization subfunction will properly execute.
 4. Zero measurement Accept/Reject counters used for display purposes.
- A. Detailed Requirements. In circumstances in which the filter vehicle position and velocity elements of the on-board filter covariance matrix are to be initialized to UVW values, the following steps shall be performed (in the order indicated):

1. Zero the entire 13 by 13 dimensional covariance matrix

$$E_{1 \text{ to } 13, 1 \text{ to } 13} = 0.0$$

2. Test the SHUTTLE_FILTER_FLAG to determine if the Shuttle vehicle or the target vehicle state is being used by the Kalman filter.

- a. If the Shuttle vehicle is the filter vehicle

(SHUTTLE_FILTER_FLAG = ON)

- (1) Call the UVW parameters initialization subfunction to initialize the position-velocity portion of the covariance matrix with the Shuttle state vector statistics (see section 4.1.2.2.1.1)

CALL: COVINIT_UVW

IN LIST: R_FILT, V_FILT

- (2) Calculate the last acceleration vector for the Shuttle vehicle for use in the covariance matrix propagation subfunction.

$$\text{TOT_ACC_LAST} = \text{ACCEL_ONORBIT}(\text{IGD}, \text{IGO}, \text{IDRAG}, \text{IVENT}, \text{ATFL_CV}, \text{R_FILT}, \text{V_FILT}, \text{T_LAST_FILT})$$

$$+ \frac{\text{DV_FILT}}{\text{DT_FILT}} \quad \text{F3}$$

F3-This equation shall be protected against division by zero(reference 3.6-3).

where IGD is the degree of the gravitational potential model, IGO is the order of the gravitational potential model, IDRAG is the drag model flag, IVENT is the vent model flag, all set by the state propagation, and ATFL_OV is from I-Load.

(For detailed requirements, see section 4.2.4.1.1)

- b. If the target vehicle is the filter vehicle

(SHUTTLE_FILTER_FLAG = OFF)

- (1) Call the UVW parameters initialization subfunction to initialize the position-velocity portion of the covariance matrix with the target state vector statistics (see section 4.1.2.2.1.1)

CALL: COVINIT_UVW

IN LIST: R_TV, V_TV

- (2) Calculate the last acceleration vector for the target vehicle for use in the covariance matrix propagation subfunction,

G_TV_LAST = ACCEL_ONORBIT (GM_DEG, GM_ORD, DFL, VFL_TV, ATFL_

TV, R_TV, V_TV, T_TV)

where GM_DEG is the degree of the gravitational potential model, GM_ORD is the order of the gravitational potential model, DFL is the drag model flag, VFL_TV is the vent model flag, and ATFL_TV is the attitude flag, all for the target vehicle.

(For detailed requirements, see section 4.2.4.1.1)

3. The covariance matrix propagation cycle counter shall be reset

I_CYCLE = 0

4. The covariance reset subfunction is called to store copies of the Shuttle state vector, the target state vector and their time tag, as well as to zero the covariance accumulated delta velocity.

CALL: COV_LAST_RESET

5. Reset the DO_NAV_LAST flags for all sensors so that the sensor bias portions of the covariance matrix will be reconfigured for active sensors

EXECUTE: DO_NAV_LAST_SETUP CODE

DO_COAS_ANGLES_NAV_LAST = OFF

DO_RR_ANGLES_NAV_LAST = OFF

DO_RRDOT_NAV_LAST = OFF

DO_ST_ANGLES_NAV_LAST = OFF

6. Reset the measurement ACCEPT/REJECT counters

(Refer to section 4.1.2.2.1.2)

CALL: DISPLAY_COUNT_INIT

B. Interface Requirements. The input and output variables for this subfunction are defined in table 4.1.2.2.1.

C. Processing Requirements. This subfunction is called by the following subfunctions:

ONORBIT_REND_AUTO_INFLIGHT_UPDATE (section 4.2.3.1)

REL_NAV_DISPLAY_UPDATES (section 4.2.3.2)

REND_NAV_INIT (section 4.1.2.2)

D. Constraints. None

E. Supplementary Information. A suggested implementation in the form of a detailed flowchart can be found in Appendix B under the name:

4.1.2.2.1.1 UVW parameters initialization (COVINIT_UVW)

The UVW parameters initialization subfunction initializes the covariance matrix when rendezvous navigation is initialized, or when an auto-inflight update or REL_NAV display update to the state vectors or covariance matrix is performed.

- A. Detailed Requirements. This subfunction has an inlist with the following internal names

INLIST: R, V

where R is the filter vehicle position vector and V is the filter vehicle velocity vector.

This subfunction performs the following steps.

1. Initialize the first six diagonal elements of the covariance with the square of prestored standard deviations.

$$E_{I,I} = \text{SIG_UPDATE}_I \text{ SIG_UPDATE}_I \text{ for } I = 1 \text{ to } 6$$

2. Initialize the off-diagonal correlation terms of the covariance matrix in the upper left 6 by 6 portion using prestored correlation coefficients along with the prestored sigmas.

$$E_{1,2} = \text{COV_COR_UPDATE}_1 \text{ SIG_UPDATE}_1 \text{ SIG_UPDATE}_2$$

$$E_{1,4} = \text{COV_COR_UPDATE}_2 \text{ SIG_UPDATE}_1 \text{ SIG_UPDATE}_4$$

$$E_{1,5} = \text{COV_COR_UPDATE}_3 \text{ SIG_UPDATE}_1 \text{ SIG_UPDATE}_5$$

$$E_{2,4} = \text{COV_COR_UPDATE}_4 \text{ SIG_UPDATE}_2 \text{ SIG_UPDATE}_4$$

$$E_{2,5} = \text{COV_COR_UPDATE}_5 \text{ SIG_UPDATE}_2 \text{ SIG_UPDATE}_5$$

$$E_{3,6} = \text{COV_COR_UPDATE}_6 \text{ SIG_UPDATE}_3 \text{ SIG_UPDATE}_6$$

$$E_{4,5} = \text{COV_COR_UPDATE}_7 \text{ SIG_UPDATE}_4 \text{ SIG_UPDATE}_5$$

$$E_{2,1} = E_{1,2}$$

$$E_{5,4} = E_{4,5}$$

3. Call the unmodeled acceleration bias and covariance initialization subfunction (section 4.2.4.1) to initialize the unmodeled acceleration bias states and the unmodeled acceleration bias slots of the covariance matrix.

CALL: U_A_BIAS_AND_COVINIT

INLIST: R, V

4. Convert the upper left 6 by 6 portion of the covariance matrix from UVW to mean of '50 coordinates with the following equations

$$E_{1to3, 1to3} = M_{UVW_M50} E_{1to3, 1to3} M_{UVW_M50}^T$$

$$E_{4to6, 4to6} = M_{UVW_M50} E_{4to6, 4to6} M_{UVW_M50}^T$$

$$E_{1to3, 4to6} = M_{UVW_M50} E_{1to3, 4to6} M_{UVW_M50}^T$$

$$E_{4to6, 1to3} = (E_{1to3, 4to6})^T$$

where the M_{UVW_M50} transformation matrix was computed by $U_A_BIAS_AND_COVINIT$.

- B. Interface Requirements. The inputs and outputs for this subfunction are given in table 4.1.2.2.1.1.
- C. Processing Requirements. This subfunction is called by
 $REND_COV_INIT$ (section 4.1.2.2.1)
- D. Constraints. None
- E. Supplementary Information. A suggested implementation of this subfunction is given by the flowchart $COVINIT_UVW$ in Appendix B.

4.1.2.2.1.2 Display parameter initialization (DISPLAY_COUNT_INIT)

The display initialization subfunction shall reset measurement ACCEPT/REJECT counters whenever the covariance initialization subfunction is invoked, whenever exiting a rendezvous navigation phase, or whenever the magnitude of the IMU sensed accelerations exceed a design dependent threshold for measurement incorporation.

- A. Detailed Requirements. The following steps shall be performed (in the order indicated):

Zero the ACCEPT/REJECT counters. N_ACCEPT (N_REJECT) is a 4x1 array which counts the total number of accepted (rejected) measurements during the current mark sequence. SEQ_ACCEPT (SEQ_REJECT) counts the number of sequential accepted (rejected) measurements during the current mark sequence.

<u>N_ACCEPT</u> = 0	
<u>N_REJECT</u> = 0	(all are 4 x 1
<u>SEQ_ACCEPT</u> = 0	dimensioned arrays)
<u>SEQ_REJECT</u> = 0	

- B. Interface Requirements. The input and output data are shown in table 4.1.2.2.1.2.

- C. Processing Requirements. This subfunction is called by the following subfunctions:

REND_COV_INIT	(section 4.1.2.2.1)
REND_NAV_EXIT	(section 4.1.1.1)
REND_BIAS_AND_COV_PROP	(section 4.2.5)

- D. Constraints. None

- E. Supplementary Information. A suggested implementation in the form of a detailed flowchart may be found in Appendix B under the name of DISPLAY_COUNT_INIT.

4.1.2.2.1.3 Covariance matrix parameters reset (COV_LAST_RESET)

The covariance matrix parameters reset subfunction saves certain navigation parameters at the end of a covariance matrix propagation subcycle for use in the next subcycle. These parameters include the Orbiter and target position and velocity vectors as well as the current time. Also, a variable used for summing the IMU sensed delta velocities over the subcycle interval is zeroed for use in the next subcycle.

A. Detailed Requirements. The following steps shall be performed:

Store the Orbiter position and velocity vectors (R_FILT, V_FILT), the target position and velocity vectors (R_TV, V_TV), last filter time (T_LAST_FILT), and zero the delta velocity accumulator (DV_COV).

R_LAST = R_FILT

V_LAST = V_FILT

R_TV_LAST = R_TV

V_TV_LAST = V_TV

DV_COV = 0.

T_COV_LAST = T_LAST_FILT

B. Interface Requirements. The input and output data are shown in table 4.1.2.2.1.3.

C. Processing Requirements. This subfunction is called by the following subfunctions:

NAV_ONORBIT_RENDEZVOUS (section 4.2.1)

REND_COV_INIT (section 4.1.2.2.1)

D. Constraints. None

E. Supplementary Information. A suggested implementation in the form of a detailed flowchart may be found in Appendix B under the name COV_LAST_RESET.

4.1.2.2.2 Target state vector reset (TARGET_RESET)

Upon entering the rendezvous navigation phase this subfunction is exercised to store the current target state vector (position and velocity) for user parameter processing. Thereafter, while still in the rendezvous navigation phase this subfunction is exercised at the end of each navigation cycle.

- A. Detailed Requirements. This subfunction shall reset the user parameter processing (section 4.5) copy of navigated target position and velocity:

R_TV_RESET = R_TV

V_TV_RESET = V_TV

- B. Interface Requirements. The input and output parameters for this subfunction are found in table 4.1.2.2.2.
- C. Processing Requirements. This subfunction is called by the following subfunctions:

NAV_ONORBIT_RENDEZVOUS (section 4.2.1)

REND_NAV_INIT (section 4.1.2.2)

- D. Constraints. None

- E. Supplementary Information. A suggested implementation of this subfunction is found in Appendix B, TARGET_RESET.

4.2 ONORBIT/RENDEZVOUS NAVIGATION PRINCIPAL FUNCTION

The Onorbit/Rendezvous Navigation principal function is the name given to the collection of all subfunctions whose major task is to supply users of this principal function with accurate estimates of the Orbiter and target state vectors. This section presents an overview of this principal function.

The Onorbit/Rendezvous Navigation principal function contains nine primary subfunctions.

- Navigation Control (section 4.2.1)
- Navigation Data Snap (section 4.2.2)
- State and Covariance Matrix Updates (section 4.2.3)
- Position and Velocity State Propagation (section 4.2.4)
- Unmodeled Acceleration State and Covariance Matrix Propagation (section 4.2.5)
- Sensor Measurement Selection (section 4.2.6)
- Sensor Measurement Initialization (section 4.2.7)
- State and Covariance Measurement Incorporation (section 4.2.8)
- Measurement Processing Statistics (section 4.2.9)

This Onorbit/Rendezvous Navigation design makes use of a Kalman filter with a 13 component state vector in order to produce an accurate estimate of position and velocity for the Orbiter and target. The state vector is composed of the following components.

- Orbiter or target position and velocity in the mean of 1950 coordinate system - six elements
- Orbiter or target unmodeled acceleration biases in mean of 1950 coordinates - three elements
- Systematic sensor biases - four elements

A flag (SHUTTLE_FILTER_FLAG) with a premission specified value determines whether the Orbiter or the target position and velocity are to be updated with the Kalman filter. This same flag also indicates which vehicle is to be associated with the unmodeled acceleration bias states.

The Navigation Control subfunction supplies the navigation trunk logic, which sequences the other eight primary subfunctions in the proper order and at the proper rates. The covariance matrix propagation, sensor selection, sensor initialization, measurement incorporation and measurement processing statistics

subfunctions can be performed at a rate slower than the data snap, state propagation and state and covariance matrix update subfunctions. This subrate is determined by the setting of the DO_FLTR_SLOW_RATE switch on the onboard REL NAV display. The switch causes the value of a cycle count, N_CYCLE, to be set to 1 of 2 I-Load values. When the cycle counter, I_CYCLE, reaches the value N_CYCLE, the slow rate subfunctions are executed. This subrate capability is basically intended to be used when it is undesirable to perform the computationally complex covariance matrix propagation and measurement incorporation at the state vector propagation rate. The Navigation Control subfunction is scheduled by the Onorbit/Rendezvous Navigation Sequencer principal function at the proper rate for the active navigation phase and operational sequence.

All external flags input to NAV are snapped at the same time and stored into locations for use by NAV. The Navigation Data Snap subfunction copies frequently changing measurement data buffers into static memory locations local to the navigation processing. During the rendezvous navigation phase, the IMU, the rendezvous radar, the star tracker, and the Crew Optical Alinement Sight (COAS) sensors are available to the navigation. During non-rendezvous, only IMU data is available.

The State and Covariance Matrix Updates subfunction implements ground updates to the Orbiter or target state vector via uplink and performs state vector transfers and covariance matrix reinitialization when requested by the crew on the REL NAV display. All of these types of updates require reinitialization of the covariance matrix. For ground updates the prediction task must be invoked to bring the Shuttle or target state vector to current time. Due to the priority of the Precise Predictor principal function in the onboard computer, the prediction can proceed only after navigation has completed a cycle. The prediction can possibly require more than one navigation interval to complete the prediction. The update to the navigation state vectors will not take place until the prediction has completed.

The Position and Velocity State Propagation subfunction must maintain a current estimate of the Orbiter position and velocity during rendezvous and non-rendezvous navigation phases and a current estimate of the target position and velocity during the rendezvous navigation phase only. The subfunction will provide a unit vector from the center of the Earth in the direction of the Sun for use by the Universal Pointing Processor principal function at a frequency of once every navigation cycle. When the powered flight navigation phase is active, IMU sensed delta velocities and a model of the Earth's gravitational acceleration are used to propagate the Orbiter position and velocity to current time. When in the coasting flight navigation phase, models of the Earth's gravitational acceleration, aerodynamic drag, and venting or uncoupled RCS thrusting acceleration are used to propagate the Orbiter. The target propagation uses models of the Earth's gravitational acceleration and aerodynamic drag during either powered flight or coasting flight.

The task of propagating the statistics of the state vector to current time as well as the propagation of the unmodeled acceleration bias states is performed by the Unmodeled Acceleration State and Covariance Matrix Propagation subfunction. The unmodeled acceleration bias state elements are propagated exponentially (the sensor bias state elements are assumed constant over the

propagation interval) so this subfunction will determine the appropriate time constant and variances used for propagation dependent on whether or not IMU sensed delta velocities were used to propagate the position and velocity vectors for the Orbiter.

The unmodeled acceleration bias states actually represent different quantities depending on whether the IMU sensed delta velocities were used to propagate the state or not. In the former case the unmodeled acceleration biases represent the errors in the IMU accelerometers. In the latter case they represent unmodeled body forces such as drag, venting and RCS uncoupled thrusting. In each case, a different time constant and variance are used for the exponentially correlated random variable statistics.

A 13 by 13 covariance matrix represents the statistics of the 13 element state vector. The position and velocity statistics are propagated using an analytic partial called the mean conic partial transition matrix. The unmodeled acceleration bias statistics and the sensor bias statistics are propagated as exponentially correlated random variables. A model of platform drift supplies state noise whenever the IMU sensed delta velocities are used to propagate the state.

The Sensor Measurement Selection subfunction must select a measurement set for processing by the Kalman filter. The following measurements are available:

- Rendezvous radar range and range rate
- Rendezvous radar shaft and trunnion angles
- Startracker horizontal and vertical angles
- Crew Optical Alinement Sight (COAS) horizontal and vertical angles

Up to four measurements can be chosen for processing - rendezvous radar range and range rate along with one pair of angles selected by the crew on the REL_NAV display. When a measurement type is selected for the first time, statistical parameters associated with the newly selected measurement type must be initialized for use in the Kalman estimation of systematic sensor biases. This task is performed by the Navigation Sensor Initialization subfunction.

The State and Covariance Measurement Incorporation subfunction performs the final step in the Kalman processing, namely, the incorporation of the selected measurements. The covariance matrix is updated. The position and velocity vectors of the vehicle state selected for Kalman processing (determined by SHUTTLE_FILTER_FLAG) are updated. The sensor biases are updated. A flag from the ILOAD (UNMOD_ACC_UPDATE_FLAG) determines whether the unmodeled acceleration states are to be updated or to be left zero, leaving only their statistical influence on the Kalman processing. Measurements can be incorporated into the state vector only when all the following criteria are satisfied.

- Rendezvous navigation phase is active (REND_NAV_FLAG = ON)
- The measurement type is selected

- The measurement data is valid
- The IMU sensed acceleration is below a premission specified threshold (MEAS_THRESHOLD)
- The covariance matrix has been propagated on the current navigation cycle
- The estimated distance between the Orbiter and the target is greater than a premission specified distance
- The measurement is not in the INHIBIT mode as selected by the crew on the REL NAV display
- The measurement does not fail to pass the edit criteria which rejects measurements which are not commensurate with the estimated measurement
- When in Major Mode 202 the MEAS_ENABLE switch is set to ON by the crew

After Kalman processing has been completed, the Measurement Processing Statistics subfunction shall compute parameters to be displayed on the REL NAV display. The parameters calculated are the measurement residuals and residual ratios, the mark histories, and the edit status.

The only direct user of the onorbit/rendezvous navigated state vector is the User Parameter Processing principal function. This principal function integrates the state vector using a high rate, less precise propagator (average-g) then that used by the navigation. The user parameter processing state vector is updated with the navigation state vector at the navigation rate. Other principal functions which require state vectors get them from the User Parameter Processing principal function at the higher rate.

In table 4.2 (the Onorbit/Rendezvous Navigation Principal Function Inputs/Outputs), there are some parameters which are being output to telemetry (TLM) which were not set by NAV. For these situations, the local source is listed as "NONE".

4.2.1 Navigation Control (NAV_ONORBIT-RENDEZVOUS)

The navigation control subfunction is responsible for providing the executive logic for the proper execution of the Onorbit/Rendezvous navigation principal function. This subfunction shall perform the following tasks.

- Store the Orbiter and target state vectors from the previous navigation cycle into protected locations for downlist
- Snap all external flags input to NAV, the IMU data, and rendezvous sensor data
- Provide for possible automatic inflight updates of either the Orbiter or target position and velocity vectors
- When in rendezvous phase, the navigation control subfunction will provide the capability to respond to crew requests, via the REL_NAV display, to reinitialize the covariance matrix or to do state vector transfers between the Orbiter position and velocity vectors and the target position and velocity vectors
- Provide for the propagation of the position and velocity vectors for the Orbiter and, when in rendezvous phase, propagate the target position and velocity vectors also
- When in rendezvous phase, this subfunction shall perform the scheduling of the asynchronous covariance propagation and will invoke the Rendezvous Bias and Covariance propagation subfunction when scheduled
- When in rendezvous phase, the navigation control subfunction will provide for the proper processing of the rendezvous sensor data. If the IMU sensed acceleration magnitude falls below a design dependent threshold, then the sensor data will be processed
- Finally, the navigation control subfunction shall invoke the Shuttle reset subfunction to store the updated Shuttle position and velocity vectors for the User Parameter Processing principal function. When in rendezvous phase, the target reset subfunction is called to store the target position and velocity vectors.

A. Detailed Requirements. This subfunction shall perform the following steps in the order indicated.

1. Execute the SNAP_INPUTS code which consists of the following tasks:

- a. Store the Orbiter and target state vectors and time tag from the previous navigation cycle into protected locations for downlist.

```

T_LAST_FILT_TLM = T_LAST_FILT
R_FILT_TLM = R_FILT
V_FILT_TLM = V_FILT
R_TV_TLM = R_TV

```

V_TV TLM = V_TV
SENSOR_BIAS_TLM = SENSOR_BIAS
UNMOD_ACC_BIAS_TLM = UNMOD_ACC_BIAS

- b. Store the external flags input to NAV and the Orbiter mass into protected locations for NAV.

NAV_ANGLES_AIF = ANGLES_AIF
 NAV_RANGE_AIF = RANGE_AIF
 NAV_RDOT_AIF = RDOT_AIF
 NAV_CURR_ORB_MASS = CURR_ORB_MASS
 NAV_DO_COVAR_REINIT = DO_COVAR_REINIT
 NAV_DO_ORB_TO_TGT = DO_ORB_TO_TGT
 NAV_DO_TGT_TO_ORB = DO_TGT_TO_ORB
 NAV_DO_OV_UPLINK = DO_OV_UPLINK
 NAV_DO_TV_UPLINK = DO_TV_UPLINK
 NAV_DO_FLTR_SLOW_RATE = DO_FLTR_SLOW_RATE
 NAV_MEAS_ENABLE = MEAS_ENABLE
 NAV_MM_202 = MM_202
 NAV_PWRD_FLT_NAV = PWRD_FLT_NAV
 NAV_RR_ANGLES_ENABLE = RR_ANGLES_ENABLE
 NAV_ST_ENABLE = ST_ENABLE

- c. Snap the measurement data input to NAV, which consist of the following steps:

- (1) Snap the IMU accumulated velocity count, time tag, and mean of 50 body quaternion as described in section 4.2.2.1.

SNAP(V_CURRENT_FILT, T_CURRENT_FILT, Q_M50BODY_IMU)

- (2) Snap the sensor measurement data as described in section 4.2.2.2. For the rendezvous radar this includes the shaft, trunnion, range and range rate measurements; the range, range rate and angle data validity flags; the mean of 50 to body attitude quaternion at the time of the snap; the time tag for the measurements; and finally a self-test indicator.

SNAP_REND_RADAR (Q_RR_SHFT, Q_RR_TRUN, Q_RR_RNG,
 Q_RR_RNG_DOT, RNG_DATA_GOOD,
 RDOT_DATA_GOOD, RR_ANGLE_DATA_GOOD,
 Q_M50BODY_RR, T_REND_RADAR, SELF_TEST_FLAG)

For startracker, snap the horizontal and vertical measurements; angle data validity flag; the mean of 50 to startracker transformation matrix; the time tag for the startracker measurements, and the target tracking mode indicator.

SNAP_STAR_TRACKER (Q_ST_HORIZ, Q_ST_VERT,
 ST_DATA_GOOD, M_M50_TO_ST, T_STAR_TRACKER,
 TRG_TRK_MODE)

For COAS, snap the horizontal and vertical angle measurements, the data validity indicator, mean of 50 to body transformation matrix at the time of COAS data snap, the COAS identification, and the COAS time tag.

SNAP COAS (Q_COAS_HORIZ, Q_COAS_VERT,
COAS_DATA_GOOD, M_M50_TO_BODY_COAS,
COAS_ID, T_COAS)

2. Convert the mean of 50 to body quaternion from the IMU into a mean of 50 to body transformation matrix by calling the quaternion to matrix function described in section 4.10.8.

$M_BODYM50 = (QUAT_TO_MAT(Q_M50BODY_IMU))^T$

3. Test the value of the DOING_REND_NAV flag to determine if rendezvous phase is active.
 - a. If the rendezvous phase is active (DOING_REND_NAV = ON), perform the following steps:
 - (1) Subtract any known time bias from the measurement time for each sensor.

$T_REND_RADAR = T_REND_RADAR - T_BIAS_REND_RADAR$
 $T_STAR_TRACKER = T_STAR_TRACKER - T_BIAS_ST$
 $T_COAS = T_COAS - T_BIAS_COAS$

- (2) Call the onorbit rendezvous auto inflight updates subfunction to perform any required ground updates to the Shuttle or target state vectors as described in section 4.2.3.1.

CALL: ONORBIT_REND_AUTO_INFLIGHT_UPDATE

- (3) Call the REL_NAV display updates subfunction to perform any required updates to the state vectors or to the covariance matrix as selected by the crew as described in section 4.2.3.2.

CALL: REL_NAV_DISPLAY_UPDATES

- (4) Invoke the onorbit rendezvous state propagation function described in section 4.2.4 to propagate the position and velocity vectors to current time.

CALL: ONORBIT_REND_R_V_STATE_PROP

- (5) Test the value of the NAV_DO_FLTR_SLOW_RATE switch.

- If the switch is on, set

$N_CYCLE = N_CYCLE_SLOW$

so that the slower of the 2 rates for processing the rendezvous measurements will be used.

- If the switch is off, set

$N_CYCLE = N_CYCLE_FAST$

so that the faster rate will be used.

- (6) Set the positive feedback flag to inform the REL NAV display which measurement processing rate is being used in navigation.

$DOING_FLTR_SLOW_RATE =$
 $NAV_DO_FLTR_SLOW_RATE$

- (7) Increment the covariance matrix propagation counter.

$I_CYCLE = I_CYCLE + 1$

Then execute the covariance propagation setup code,

EXECUTE: COV_PROP_SETUP CODE,

which consists of the following tasks:

- If IMU sensed delta velocity was used by the state propagation subfunction on the present navigation cycle (USE_IMU_DATA = ON) then accumulate the delta velocity into the total delta velocity for the covariance propagation interval and set the covariance powered flight indicator to ON.

$DV_COV = DV_COV + DV_FLT$

$COV_PWRD_FLT = ON$

- If the contact acceleration (CONT_ACC) for the Shuttle is greater than a design dependent threshold for measurement processing (CONT_ACC MEAS_THRESHOLD) then a flag is set to indicate that measurements will not be processed on the current covariance propagation subcycle.

$NOISY_NAV_MEAS = ON$

- (8) If the covariance matrix propagation cycle counter is greater than or equal to the covariance propagation subcycle count (I_CYCLE - N_CYCLE) then perform the following tasks:

- Zero the cycle counter

$I_CYCLE = 0$

- Call the rendezvous bias and covariance matrix propagation subfunction described in section 4.2.5.

CALL: REND_BIAS_AND_COV_PROP

This subfunction propagates the covariance matrix and propagates the ECRV bias statistics and sets a flag (NAV_MEAS) which determines whether sensor measurements will be incorporated into the state vector on the current covariance propagation cycle.

- (9) If the unmodeled acceleration bias and covariance propagation sub-function has set NAV_MEAS = ON, i.e., NOISY_NAV_MEAS = OFF and we are on a covariance propagation cycle, the measurements shall be processed on this cycle by performing the following tasks.

- Call the sensor measurement selection subfunction to select a measurement set for processing as described in section 4.2.6.

CALL: REND_SENSOR_SELECT

- Call the sensor measurement initialization subfunction to initialize filter statistics and sensor bias states for newly selected measurement types as described in section 4.2.7.

CALL: REND_NAV_SENSOR_INIT

- Call the rendezvous radar range and range rate measurement subfunction as described in section 4.2.8.1.

CALL: RRDOT_NAV

This subfunction incorporates the rendezvous radar range and range rate measurements using the Kalman filter update equations. Increment the mark counter for downlist.

RRDOT_MARK_NUM = RRDOT_MARK_NUM+1

- If rendezvous radar angles have been selected for processing (DO_RR_ANGLES_NAV = ON) then call the rendezvous radar angles measurement subfunction described in section 4.2.8.2.

CALL: RR_ANGLE_NAV

This subfunction incorporates the rendezvous radar shaft and trunnion measurements using the Kalman update.

Increment the mark counter for this measurement

RR_ANGLE_MARK_NUM = RR_ANGLE_MARK_NUM+1

Otherwise (DO_RR_ANGLES_NAV = OFF), if startracker angles have been selected (DO_ST_ANGLES_NAV = ON) then call the startracker angles measurement subfunction described in section 4.2.8.3.

CALL: STAR_TRACKER_NAV

This subfunction incorporates the horizontal and vertical startracker measurements by using the Kalman filter update equations.

Increment the mark counter for this measurement

ST_MARK_NUM = ST_MARK_NUM+1

Otherwise (DO_RR_ANGLES_NAV = OFF and DO_ST_ANGLES_NAV = OFF), call the COAS angles measurement subfunction described in section 4.2.8.4.

CALL: COAS_NAV

This subfunction incorporates the horizontal and vertical COAS measurements using the Kalman update equations.

Increment the mark counter for this measurement

COAS_MARK_NUM = COAS_MARK_NUM+1

- Call measurement processing statistics to calculate display parameters as described in section 4.2.9.

CALL: MEAS_PROCESSING_STATISTICS_REND

- Set the measurement processing indicator to OFF

NAV_MEAS = OFF

- (10) If the covariance matrix was propagated on this navigation cycle (I_CYCLE = 0) then call the covariance matrix parameters reset subfunction.

CALL: COV_LAST_RESET

- (11) Call the target state vector reset subfunction to reset the user parameter processing state vector as described in section 4.1.2.2.2.

CALL: TARGET_RESET

- (12) Call the Orbiter state vector reset subfunction to reset the user parameter processing state vector as described in section 4.1.2.1.

CALL: SHUTTLE_RESET

- b. If the rendezvous phase is not active (DOING_REND_NAV = OFF) then the following steps shall be performed.

- (1) Repeat step (2) under Item a, i.e., call the onorbit rendezvous auto inflight updates to perform any required ground updates to the Shuttle or target position and velocity vectors.

CALL: ONORBIT_REND_AUTO_INFLIGHT_UPDATE

- (2) Invoke the onorbit rendezvous state propagation subfunction (see section 4.2.4) to propagate the Orbiter position and velocity vectors to current time.

CALL: ONORBIT_REND_R_V_STATE_PROP

- (3) Repeat step (12) under Item a, i.e., call the Orbiter State Vector Reset subfunction to reset the user parameter processing Orbiter state vector as described in section 4.1.2.1.

CALL: SHUTTLE_RESET

- B. Interface Requirements. The inputs and outputs for this subfunction are listed in table 4.2.1.

- C. Processing Requirements. This subfunction is called by ONORBIT_REND_NAV SEQUENCER (section 4.1.1).

- D. Constraints. None

- E. Supplementary Information. During OPS 8 rendezvous navigation cannot be active, hence it is not necessary to implement the DOING_REND_NAV = ON branch of the logic for the OPS 8 computer load.

A suggested implementation of this subfunction can be found in Appendix B.

4.2.2 Navigation Data Snap

The Onorbit/Rendezvous navigation principal function shall accomplish the task of snapping navigation data to obtain Orbiter IMU-sensed accumulated velocities, the current attitude quaternion, and sensor data from the rendezvous radar, the star tracker, and the crew optical alignment sight (COAS). The total accumulated sensed velocity is required to account for nongravitational accelerations during integration of Orbiter equations of motion. The sensor data are collected and stored for use in navigation processing during the rendezvous navigation phase.

4.2.2.1 IMU and Attitude Data Snap

The IMU and attitude data snap task will provide the capability to obtain Orbiter IMU-sensed accumulated velocities (expressed in M50 coordinates) and the current attitude quaternion, along with their associated GMT time tag. These data will be obtained through IMU RM/SOP and stored for use in the navigation and user parameter propagation subfunctions.

- A. Detailed Requirements. Data from at least one good IMU are required as indicated in the following example:

SNAP (V_IMU_SNAP, T_IMU)

where V_IMU_SNAP and T_IMU are respective copies of IMU-sensed accumulated velocities and their associated time tag in the user parameter state propagation.

If a consistent set of IMU and attitude data are required, this is indicated by the following second example:

SNAP (V_CURRENT_FILT, T_CURRENT_FILT, Q_M50BODY_IMU)

where V_CURRENT_FILT and T_CURRENT_FILT are respective copies of IMU-sensed accumulated velocities, their associated time tag, and mean of 50 to body quaternion in the navigation control subfunction.

- B. Interface Requirements. The parameter crossreference table between IMU RM/SOP names and their copies of Onorbit/Rendezvous navigation variables is shown in table 4.2.2.1.
- C. Processing Requirements. The data from IMU RM/SOP (time tag, accumulated velocities, and attitude quaternions) must be made available for the collection and storage process. The collection rate is indicated by the onorbit/rendezvous navigation sequencer. However, this rate assumes that the available data are fresh. This implies that SOP's processing must be at a rate equal to or greater than the collection rate. This data snap is called by

NAV_ONORBIT_RENDEZVOUS	(section 4.2.1)
ONORBIT_REN_USER_PARAM_STATE_PROP	(section 4.5.1)
OPS_2_OR_8_INITIALIZE	(section 4.1.2)

- D. Constraints. The data collections should occur after a complete current set is available and just prior to use in navigation in order to supply current data.
- E. Supplementary Information. The snap statement above implies the assignment of current IMU RM/SOP values to the variable names shown in parentheses. The suggested implementation of this subfunction is not described in this document because the discussion involves the processor level interface design concept, which is beyond the scope of this document. However, extreme care must be exercised to provide sequentially time homogeneous data set to the appropriate subfunctions.

ONORBIT/REND NAVIGATION VARIABLES, AND USER
PARAMETER PROCESSING VARIABLES

IMU RM & IMU SOP	ONORBIT/REND NAV	USER PARAMETER PROCESSING
T_IMUS_GA	T_CURRENT_FILT	T_IMU
V_IMU_CURRENT	V_CURRENT_FILT	V_IMU_SNAP
Q_BOD_M50	Q_M50BODY_IMU	

4.2.2.2 Rendezvous Sensor Data Snap

During the rendezvous navigation phase, this subfunction collects and stores sensor data from the rendezvous radar, the star tracker, and the crew optical alignment sight (COAS).

The purpose of the rendezvous sensor data snap is to properly save the data sets used in navigation processing for use in the appropriate rendezvous sensor navigation subfunction (section 4.2.8) whereas the actual data may continue to be refreshed by hardware sensor reading and sensor SOP processing.

A. Detailed Requirements.-- During the rendezvous navigation phase, data from the external sensors, together with the corresponding data good flags, associated time tags, and the appropriate attitude information valid at those times shall be obtained. A premission-loaded time bias shall then be subtracted from the time tag for each sensor. The equations are:

1. For the rendezvous radar:

SNAP_REND_RADAR (Q_RR_SHFT, Q_RR_TRUN, Q_RR_RNG, Q_RR_RNG_DOT,
RNG_DATA_GOOD, RDOT_DATA_GOOD, RR_ANGLE_DATA_GOOD, Q_M50BODY_RR,
T_REND_RADAR, SELF_TEST_FLAG)

where Q_RR_SHFT is the shaft angle measurement

Q_RR_TRUN is the trunnion angle measurement

RR_ANGLE_DATA_GOOD is the validity flag of the above measurements

Q_RR_RNG is the radar range measurement

RNG_DATA_GOOD is the respective data good flag

Q_RR_RNG_DOT is the radar range rate reading

RDOT_DATA_GOOD is the respective validity indicator

T_REND_RADAR is the time at which these measurements are considered to have been effected

Q_M50BODY_RR is the gimbal angle quaternion array

SELF_TEST_FLAG is the flag indicating whether the rendezvous radar is operating in the self-test mode

$$T_REND_RADAR = T_REND_RADAR - T_BIAS_REND_RADAR$$

2. For the star tracker,

SNAP_STAR_TRACKER (Q_ST_HORIZ, Q_ST_VERT, ST_DATA_GOOD,
M_M50_TO_ST, T_STAR_TRACKER, TRG_TRK_MODE)

where:

Q_ST_HORIZ is the horizontal angle measurement

Q_ST_VERT is the vertical angle measurement

ST_DATA_GOOD is the data good flag relative to these angle measurements

M_M50_TO_ST is the M50-to-star tracker sensor coordinate system rotation matrix at the time T_STAR_TRACKER

T_STAR_TRACKER is the time tag

TRG_TRK_MODE is the flag indicating whether the star tracker is in the target tracking mode

$$T_STAR_TRACKER = T_STAR_TRACKER - T_BIAS_ST$$

3. For the COAS,

SNAP COAS (Q_COAS_HORIZ, Q_COAS_VERT, COAS_DATA_GOOD, M_M50_TO_BODY_COAS, COAS_ID, T_COAS)

where:

Q_COAS_HORIZ is the horizontal angle measurement

Q_COAS_VERT is the vertical angle measurement

COAS_DATA_GOOD is the data good flag relative to these angle measurements

COAS_ID is the COAS select indicator

T_COAS is the time of the measurement

M_M50_TO_BODY_COAS is the M50-to-COAS sensor coordinate system transformation matrix at the time T_COAS

$$T_COAS = T_COAS - T_BIAS_COAS$$

- B. Interface Requirements.- The parameter name cross reference between rendezvous radar SOP and Onorbit/Rendezvous Navigation variables is shown in table 4.2.2.2-1. The cross reference table between star tracker SOP and Onorbit/Rendezvous Navigation variables is given in table 4.2.2.2-2.
- C. Processing Requirements.- The data from the sensors (measurements, ID's, validity flags, rotation matrices, and time tags) must be made available for the collection and storage process. The collection rate (not necessarily sensor interrogations) is indicated by the Onorbit/Rendezvous Navigation Sequencer. However, this rate assumes that the available data are fresh.

This implies that SOP's processing must be at a rate equal to or greater than the collection rate. This data is called by NAV_ONORBIT_RENDEZVOUS (section 4.2.1).

- D. Constraints.-- The data collections should occur after a complete current set is available and just prior to use in navigation in order to supply current data.
- E. Supplementary Information.-- The snap statement above implies the assignment of current SOP values to the variable names shown in parentheses. The suggested implementation of this subfunction is not described in this document because the discussion involves the processor level interface design concept which is beyond the scope of this document. However, extreme care must be exercised to provide sequentially time homogeneous data sets to the appropriate subfunctions.

4.2.3 State and Covariance Matrix Updates

The Onorbit/Rendezvous Navigation principal function shall provide for the capability to perform automatic inflight updates of the Orbiter and/or target position and velocities, crew requested covariance matrix reinitialization, and crew requested state vector transfers. The capability to perform the position-velocity update of either the Orbiter or target will be handled by the automatic inflight updates subfunction while the capability to handle crew requests for state vector transfers and covariance matrix reinitialization will be done by the REL NAV display updates subfunction.

4.2.3.1 Auto Inflight Updates (ONORBIT_REND_AUTO_INFLIGHT UPDATE)

The automatic inflight updates subfunction shall determine when an update to the shuttle or target state vector is required by the ground and then schedule the state vector prediction task to predict the uplinked state vectors to the time tag T_RESET, established by the Orbiter state vector reset subfunction (see section 4.1.2.1). If a state vector update has occurred during rendezvous navigation phase, the covariance matrix shall be reinitialized.

A. Detailed Requirements.

1. First, a local flag SV_UPDATE, which indicates whether a state vector update has occurred, is set to OFF.
2. If the ground has indicated that the Orbiter vector is uplinked (NAV_DO_OV_UPLINK = ON) then the following tasks will be performed in the order indicated.
 - a. The prediction task indicator flag, PRED_USE, is interrogated for a zero value to determine if the state vector prediction task is available for scheduling. If the state vector prediction task is available then the following tasks are performed.
 - (1) The following parameters are defined preceding the scheduling of the state vector prediction task:

```

PRED_USE = 1
OV_PREDICT_FAIL = OFF
PRED_ORB_MASS = NAV_CURR_ORB_MASS
PRED_ORB_AREA = REF_ORB_AREA
PRED_ORB_CD = REF_ORB_CD
GMDF = GM_DEG
GMOP = GM_ORD
DMP = DFL
VMP = VFLOV_PRED
ATMP = 1
PRED_STEP = PREC_STEP_PRED
R_PRED_INIT = R_GND
V_PRED_INIT = V_GND
T_PRED_INIT = T_GND

```

(2) Next, the state vector prediction task is scheduled.

SCHEDULE: STATE_VECTOR_PREDICT_TASK

- b. If the PRED_USE flag is nonzero, it is tested for a value of 3 which indicates that the state vector prediction task has determined that the prediction interval is too large; hence no prediction will take place. If PRED_USE = 3 then the following flags are set.

PRED_USE = 0, indicating the state vector prediction task is available.

DO_OV_UPLINK = OFF

OV_PREDICT_FAIL = ON, indicating that no prediction will take place for the Orbiter state vectors.

- c. If the PRED_USE flag is not set to 3 then it is tested for a value of 2 which indicates that the state vector prediction task has successfully predicted the Orbiter state vector. If PRED_USE = 2 then the following actions are taken.

PRED_USE = 0, indicating that the state vector prediction task is available.

T_LAST_FILT = T_PRED_FINAL predicted Orbiter

R_FILT = R_PRED_FINAL vectors and time tag

V_FILT = V_PRED_FINAL are stored.

SV_UPDATE = ON, indicating that an inflight update has taken place.

T_ORB_STATE_UPDATE

= T_LAST_FILT, the time tag of the inflight update is saved for downlist.

DO_OV_UPLINK = OFF

3. If the ground has indicated that the target vector is uplinked (NAV_DO_TV_UPLINK = ON) then the DOING_REND_NAV flag and the PRED_USE flags are interrogated to determine if the uplinked target state vectors are to be stored or if the target state prediction logic should be exercised.

- a. If rendezvous navigation is active, DOING_REND_NAV = ON, or the target state prediction logic is in progress, PRED_USE ≥ 7, then the PRED_USE flag is tested to determine the appropriate action to follow.

- (1) If PRED_USE = 0, target prediction is to be scheduled. The following actions are taken:

- The prediction parameters are initialized.

PRED_USE = 7

TV_PREDICT_FAIL = OFF

GMDP = GM_DEG

GMOP = GM_ORD
 DMP = DFL
 VMP = VFLTV_PRED
 ATMP = ATFL_TV
 PRED_STEP = PREC_STEP_PRED
 R_PRED_INIT = R_TV_GND
 V_PRED_INIT = V_TV_GND
 T_PRED_INIT = T_TV_GND

- The state vector prediction task is scheduled.

SCHEDULE: STATE_VECTOR_PREDICT_TASK

- (2) If the PRED_USE flag is equal to 9, the state vector prediction task has determined that the prediction interval is too large; hence no prediction will take place. The following flags are set.

PRED_USE = 0, indicating the state vector prediction task is available.

DO_TV_UPLINK = OFF

TV_PREDICT_FAIL = ON, indicating that no prediction will take place for the target state vectors.

- (3) If the PRED_USE flag is equal to 8, the state vector prediction task has successfully predicted the target state vectors. The following actions are taken.

PRED_USE = 0, indicating that the state vector prediction task is available.

T_TV = T_PRED_FINAL predicted target vectors and
 R_TV = R_PRED_FINAL time tag are stored.

V_TV = V_PRED_FINAL

SV_UPDATE = ON, indicating that an inflight update has taken place.

T_TV_STATE_UPDATE

= T_TV, the time tag of the inflight update is saved for downlist.

DO_TV_UPLINK = OFF

- b. If rendezvous navigation phase is not active, DOING_REND_NAV = OFF, and the target state prediction task is not in progress for an inflight update, PRED_USE < 7, then the uplinked state vector and associated time tag are stored, the time of the uplink is stored, and the DO_TV_UPLINK flag is turned OFF.

T_TV = T_TV_GND

R_TV = R_TV_GND

V_TV = V_TV_GND

T_TV_STATE_UPDATE = T_TV

DO_TV_UPLINK = OFF

4. Finally, the covariance initialization subfunction is invoked if the SV_UPDATE flag is ON and DOING_REND_NAV = ON, indicating that the rendezvous navigation phase is active.

CALL: REND_COV_INIT

- B. Interface Requirements. The inputs and outputs for this subfunction are given in table 4.2.3.1.

- C. Processing Requirements. This subfunction is called by

NAV_ONORBIT_RENDEZVOUS (section 4.2.1)

- D. Constraints. None

- E. Supplementary Information. A suggested implementation of this subfunction is given in Appendix B.

*Onorbit/Rendezvous principal function, see section 4.2
 **Initialization parameters, see section 4.7

4.2.3.1.1 State vector prediction task (STATE_VECTOR_PREDICT_TASK).- It is a requirement that the execution of either the Onorbit/Rendezvous Sequencer or the Onorbit/Rendezvous Navigation principal function has priority over the execution of the Onorbit Precision State Prediction principal function. The purpose of the state vector prediction task is to provide logic, to be executed at the same priority as the predictor, which will allow the navigation and sequencer principal functions to execute in a nominal manner despite delays in the predictor due to its low priority execution.

This task shall be scheduled by the Rendezvous Navigation Initialization subfunction and the Auto Inflight Updates subfunction to provide for the prediction of either the Orbiter and/or target state vectors to the time tag specified by the Orbiter State Vector Reset subfunction. The state vector prediction task shall also test the prediction interval size against a gross reasonability design dependent threshold to prevent the Onorbit Precision State Prediction principal function from predicting over inordinately large time intervals. The state vector prediction task shall also set the value of the PRED_USE flag which indicates the status of prediction to the scheduling subfunction. The PRED_USE flag has the following values.

<u>Value of PRED USE</u>	<u>Definition</u>
0	Prediction task is available for scheduling
1	Prediction task scheduled for Orbiter inflight update
2	Prediction task completed for Orbiter inflight update
3	Prediction task failed for Orbiter inflight update
4	Prediction task scheduled for rendezvous navigation initialize
5	Prediction task completed for rendezvous navigation initialize
6	Prediction task failed for rendezvous navigation initialize
7	Prediction task scheduled for target inflight update
8	Prediction task completed for target inflight update
9	Prediction task failed for target inflight update

The scheduling subfunction will set PRED_USE to the values of 0, 1, 4, or 7. All other values are set by the prediction task.

A. Detailed Requirements.

1. A local flag, PRED_TASK_COMPLETE, which signals when the prediction task is completed, is initialized to OFF upon entering the state vector prediction task.

PRED_TASK_COMPLETE = OFF

2. Next, the absolute value of the difference between the initial prediction time tag, T_PREDICT_INIT, and the time tag T_RESET is tested against a gross reasonability (design dependent) threshold in order to prevent the Onorbit Precision State Prediction principal function from predicting over excessively large time intervals.

$$|T_PRED_INIT - T_RESET| > MAX_TIME_TOL$$

- a. If the time threshold is exceeded then the flag PRED_USE is incremented by 2 in order to communicate to the invoking subfunction that the prediction task has failed.

$$PRED_USE = PRED_USE + 2$$

- b. If the maximum time tolerance MAX_TIME_TOL is not exceeded, then the following logic (steps (1), (2), (3), and (4)) is executed in a cyclic fashion until the PREDICT_TASK_COMPLETE flag is turned ON.

DØ UNTIL
PREDICT_TASK_COMPLETE = ON

- (1) First, the time tag for the final predicted state vectors is set to the current value of T_RESET as defined by the navigation task.

$$T_PRED_FINAL = T_RESET$$

- (2) Next, the Onorbit Precision State Prediction principal function is invoked.

CALL: ONORBIT_PREDICT

- (3) The predicted state vectors and time tag are saved for the next state vector prediction task cycle.

$$\begin{aligned} R_PRED_INIT &= R_PRED_FINAL \\ V_PRED_INIT &= V_PRED_FINAL \\ T_PRED_INIT &= T_PRED_FINAL \end{aligned}$$

- (4) Using NAV's current value for T_RESET, the prediction interval magnitude is tested against a hard coded time tolerance SV_TIME_TAG_DIFF to determine if the predicted vectors are close to the time tag T_RESET.

$$|T_PRED_INIT - T_RESET| < SV_TIME_TAG_DIFF$$

(It should be noted that any value for SV_TIME_TAG_DIFF which is smaller than the length of a single navigation cycle will cause the predictor task to predict to current time (T_RESET).)

If the predicted state vector time tag is close to the current reset time tag (i.e., less than or equal to SV_TIME_TAG_DIFF), then the prediction complete flag is set to ON and the PRED_USE flag is incremented by one to indicate to the proper navigation subfunction that the prediction task is completed and predicted state vectors are available.

PRED_TASK_COMPLETE = ON

PRED_USE = PRED_USE + 1

Steps (1), (2), (3), and (4) are repeated until PRED_TASK_COMPLETE is ON as specified in step b.

- B. Interface Requirements. Input and output parameters for the state vector prediction task are specified in table 4.2.3.1.1. Since the STATE_VECTOR_PREDICT_TASK (SVPT) executes in parallel to the navigation task, the value of T_RESET can update in NAV while the SVPT is in process. The SVPT makes cyclic use of T_RESET in two places in its logic and should be provided NAV's current value of T_RESET each time it uses the parameter.
- C. Processing Requirements. The following subfunctions schedule the state vector prediction task.
 - Rendezvous Navigation Initialization
(REND_NAV_INIT, Section 4.1.2.2)
 - Auto Inflight Updates
(ONORBIT_REND_AUTO_INFLIGHT_UPDATE, Section 4.2.3.1)
- D. Constraints. The STATE_VECTOR_PREDICT_TASK is one of several users of the onorbit predictor. Since the same compool locations are used by all users of this principal function for setup and output and since the use of the predictor by the STATE_VECTOR_PREDICT_TASK may be interrupted by other users, it is required that its predictor parameters be protected from alteration by other users during execution of this principal function.
- E. Supplemental Information. A suggested implementation of the state vector prediction task may be found in the Appendix B flowchart STATE_VECTOR_PREDICT_TASK.

4.2.3.2 REL_NAV Display Updates (REL_NAV_DISPLAY_UPDATES)

This subfunction is required to respond to crew request, made via item entries on the REL_NAV display, to reinitialize the covariance matrix or to perform a state vector transfer from the Orbiter state vector to the target state vector, or vice versa. This subfunction is exercised on each state vector propagation cycle by the NAV control logic.

- A. Detailed Requirements. The following steps shall be performed (in the order indicated) in response to crew request while rendezvous navigation is active:

1. Turn off the positive feedback flags to the REL_NAV display.

DID_COVAR_REINIT = OFF

DID_ORB_TO_TGT = OFF

DID_TGT_TO_ORB = OFF

2. Test the NAV_DO_COVAR_REINIT flag to determine if the crew has requested that the covariance matrix be reinitialized. If NAV_DO_COVAR_REINIT = ON, perform the following steps:

- a. Call the covariance matrix initialization subfunction to reinitialize the covariance matrix, to zero the unmodeled acceleration states, and compute the total filter vehicle acceleration vector (see section 4.1.2.2.1):

CALL: RECD_COV_INIT

- b. Reset the covariance matrix initialization indicator flag and the positive feedback flag (to the REL_NAV display) as follows:

DO_COVAR_REINIT = OFF

DID_COVAR_REINIT = ON

3. Test the NAV_DO_ORB_TO_TGT flag to determine if the crew has requested a state vector transfer (Orbiter to target).

- a. If NAV_DO_ORB_TO_TGT = ON, the following steps are taken:

- (1) The target state vectors are set equal to the Orbiter state vectors:

R _TV = R _FILT

V _TV = V _FILT

- (2) The covariance matrix initialization subfunction is called to reinitialize the covariance matrix, to zero the unmodeled acceleration states, and compute the total filter vehicle acceleration vector (see section 4.1.2.2.1):

CALL: REND_COV_INIT

- (3) The flags indicating the Orbiter-to-target state vector transfer and the positive feedback (to the REL_NAV display) shall be set:

DO_ORB_TO_TGT = OFF

DID_ORB_TO_TGT = ON

- b. If the NAV_DO_ORB_TO_TGT flag is off, test the NAV_DO_TGT_TO_ORB flag to determine if the crew has requested a state vector transfer (target to Orbiter). If NAV_DO_TGT_TO_ORB = ON, the following steps are taken:

- (1) The Orbiter state vector shall be set equal to the target state vector:

R_FILT = R_TV

V_FILT = V_TV

- (2) The covariance matrix initialization subfunction is called to reinitialize the covariance matrix, to zero the unmodeled acceleration state, and compute the total filter vehicle acceleration vector (see section 4.1.2.2.1):

CALL: REND_COV_INIT

- (3) The flags indicating target-to-Orbiter state vector transfer and the positive feedback (to the REL_NAV display) shall be set:

DO_TGT_TO_ORB = OFF

DID_TGT_TO_ORB = ON

- B. Interface Requirements. Input and output parameters are listed in table 4.2.3.2.

- C. Processing Requirements. This subfunction is called by

NAV_ONORBIT_RENDEZVOUS (section 4.2.1)

- D. Constraints. Covariance matrix reinitialization as well as the state vector transfer must be activated via crew input to the REL_NAV display and only while the Rendezvous Navigation principal function is active.

- E. Supplementary Information. A suggested implementation in the form of a detailed flowchart can be found in Appendix B under the name:

REL_NAV_DISPLAY_UPDATES

4.2.4 Position and Velocity State Propagation (ONORBIT_REND_R_V_STATE_PROP)

The position and velocity state propagation subfunction is contained within the Onorbit/Rendezvous Navigation principal function and is used to perform a number of tasks related to the propagation of the Orbiter and target vehicle state vectors. The subfunction will be employed to propagate the Orbiter and target vehicle state vectors from the time of the previous navigation cycle to the current navigation cycle time.

Prior to state vector propagation, the task of snapping IMU and attitude data shall be performed to obtain the current time (T_CURRENT_FILT), accumulated IMU sensed velocity (V_CURRENT_FILT), and an attitude quaternion (Q_MSOBODY_IMU). For detailed requirements of these data snaps, see IMU and Attitude Data Snap, section 4.2.2.1.

During vehicle state propagation, various acceleration models are available for use in the determination of perturbing acceleration values and include gravitational accelerations (always used) and nongravitational accelerations (drag, and a limited venting and uncoupled RCS thrusting model). The nongravitational acceleration models shall be used only when the vehicle sensed acceleration (DV_FILT), obtained from the IMU accumulated sensed velocity (V_CURRENT_FILT), is judged to be insignificant; that is, below a predetermined value (DA_THRESHOLD_TEST). A detailed description of the acceleration models may be found in section 4.2.4.1.1. State vector propagation will employ only 1 scheme for integration of the equations of motion, the SUPER G algorithm (see section 4.2.4.1). This algorithm will be used for propagating both the Orbiter and target state vectors in both coasting and powered flight.

- A. Detailed Requirements.- The computations that shall be performed for propagation of the position and velocity vectors are initiated by a call to the Onorbit/Rendezvous position and velocity state propagation subfunction (ONORBIT_REND_R_V_STATE_PROP) in the following form:

CALL: ONORBIT_REND_R_V_STATE_PROP

The following will be performed in the order indicated.

1. The IMU navigation acceleration threshold value initialized by ILOAD and updated by the crew on the IMU ALIGN DISPLAY will be loaded into the DA_THRESHOLD parameter:

DA_THRESHOLD = IMU_NAV_ACCEL_THRESH

2. The acceleration model flags shall be set up for Orbiter coasting flight propagation:

IGD = GM_DEG
IGO = GM_ORD
IDRAG = 1
IVENT = 1

3. Next the change in velocity (DV_FILT) and the corresponding time interval (DT_FILT) used in the advancement of both Orbiter and target state vectors shall be calculated by subtraction of the previous cycle values (V_LAST_FILT and T_LAST_FILT) from the current IMU snapped values.

$$\begin{aligned}\underline{DV_FILT} &= \underline{V_CURRENT_FILT} - \underline{V_LAST_FILT} \\ \underline{DT_FILT} &= \underline{T_CURRENT_FILT} - \underline{T_LAST_FILT}\end{aligned}$$

4. An acceleration averaged over the desired interval is next determined by:

$$\underline{CONT_ACC} = |\underline{DV_FILT}| / \underline{DT_FILT} \quad F3$$

5. Next the powered flight navigation flag, NAV_PWRD_FLT_NAV, shall be tested, and flags specifying the acceleration models to be used to propagate the Orbiter state vector on this navigation cycle shall be defined.
- a. If the NAV_PWRD_FLT_NAV flag is found to be ON, acceleration threshold tests must be made to determine the acceleration models to be used in propagating the Orbiter state vector. The procedure is as follows:

- (1) Convert the DA_THRESHOLD value from micro g's to feet/sec², normalize according to the propagation time interval (DT_FILT), and store the new value into DA_THRESHOLD_TEST.

$$\underline{DA_THRESHOLD_TEST} = \underline{DA_THRESHOLD} (GO) (10^{-6}) / \underline{DT_FILT} \quad F3$$

("GO" is the micro G's to feet/sec² conversion factor.)

- (2) Test the acceleration value (CONT_ACC) against the converted threshold value, DA_THRESHOLD_TEST.

- If CONT_ACC > DA_THRESHOLD_TEST, turn the IMU data-use flag ON and set the flags for modeling drag and vent forces to 0 (OFF).

USE_IMU_DATA = ON
IDRAG = 0
IVENT = 0

- Otherwise, set the IMU data-use flag to OFF, and force the accumulated velocity for the propagation interval to zero.

USE_IMU_DATA = OFF
DV_FILT = 0.

F3 This equation shall be protected against division by zero (Reference 3.6-3).

(3) Test the acceleration value (CONT_ACC) against the ILOADED MEAS_THRESHOLD value to determine if the powered flight gravitational potential model should be used.

- If CONT_ACC > MEAS_THRESHOLD, use the powered flight values for the potential models

IGD = GM_DEG_LOW

IGO = GM_ORD_LOW

- Otherwise, the gravitational parameters will remain set to the free flight values.

b. In the situation where the NAV_PWRD_FLT_NAV is found to be OFF, the Orbiter sensed acceleration is not used in propagating the Orbiter state vector. Therefore, set

DV_FILT = 0.

USE_IMU_DATA = OFF

6. Next the SUPER_G algorithm is called to propagate the Orbiter state vector, using the acceleration models computed above.

CALL: SUPER_G

IN LIST: IGD,IGO,IDRAG,IVENT,ATFL_OV,R_FILT,V_FILT,T_

LAST_FILT,T_CURRENT_FILT,DT_FILT,DV_FILT

OUT LIST: R_FILT,V_FILT,G_NEW

The values of R_FILT and V_FILT output by SUPER_G are the required propagated position and velocity vectors of the Orbiter during a powered or coasting flight mode. The vector G_NEW is a modeled total acceleration vector obtained according to the specified flag settings and corresponding to R_FILT, V_FILT and T_CURRENT_FILT.

7. Once the Orbiter state vector has been propagated, the DOING_REND_NAV flag will be tested to determine if propagation of the target vehicle state is required.

```

|
|DOING_REND_NAV
|

```

If the DOING_REND_NAV flag is ON, the target vehicle state vector will be propagated to time T_CURRENT_FILT from time T_TV using the SUPER_G algorithm.

CALL: SUPER_G

IN LIST: GM DEG, GM ORD, DFL, VPL TV, ATFL TV,
R_TV, V_TV, T_TV, T_CURRENT_FILT, DT_FILT,
TDV_FILT

OUT LIST: R_TV, V_TV, G_TV

The out list variables represent the required advanced target vehicle state vector and total target acceleration vector. Here R_TV is the target position vector, V_TV the target velocity vector, and G_TV the corresponding acceleration vector, all determined for the time T_CURRENT_FILT.

The time T_CURRENT_FILT is saved as T_TV.

T_TV = T_CURRENT_FILT

8. After satisfaction of the operations caused by the DOING_REND_NAV flag value, T_LAST_FILT and V_LAST_FILT will be updated to T_CURRENT_FILT and V_CURRENT_FILT in preparation for the next cycle through ONORBIT_REND_RV_STATE_PROP.

T_LAST_FILT = T_CURRENT_FILT
V_LAST_FILT = V_CURRENT_FILT

9. A call to the solar ephemeris subfunction will provide sine and cosine functions of the sun's current position preparatory to calculation of the Earth-sun unit vector. The unit vector will be constructed as follows:

(a) CALL: SOLAR_EPHEM

IN LIST: T_CURRENT_FILT

OUT LIST: SDEC, CDEC1, COS_SOL_RA, SIN_SOL_RA

(b) UR_SUN₁ = COS_SOL_RA CDEC1
UR_SUN₂ = SIN_SOL_RA CDEC1
UR_SUN₃ = SDEC

The solar unit vector is required by the Universal pointing processing principal function.

- B. Interface Requirements.- Input and output parameters for the position and velocity state propagation subfunction trunk logic are given in table 4.2.4.
- C. Processing Requirements.- This subfunction shall be called by the Onorbit/Rendezvous Navigation principal function (NAV_ONORBIT_RENDEZVOUS).

D. Constraints. - The following constraints apply:

1. The acceleration models task is needed not only by the navigation state propagation subfunction, but also by the Onorbit Precision State Prediction principal function and by the User Parameter state propagation subfunction. Each user of acceleration models shall set its own flags and therefore requires a different calculation. To protect against interference in the acceleration computations, it is important that these computations not be interrupted.
2. The current Orbiter mass (CURR_ORB_MASS) will be initialized for use by NAV by the Onorbit/Rendezvous Navigation Sequencer principal function and will be maintained for NAV by the Onorbit Guidance principal function.

E. Supplementary Information. - A suggested implementation of this subfunction in the form of detailed flow diagrams may be found in Appendix D under the following:

ONORBIT_REND_R_V_STATE_PROP

4.2.4.1 Position and Velocity Propagation (SUPER_G)

During powered flight navigation phases, the equations of motion used for Orbiter state propagation have the form of a Taylor series truncated at the term in h^3 , where h is the step size. The integration scheme used, called SUPER_G, is an improved version of the AVERAGE_G method, containing a correction cycle.

During Orbiter powered flight conditions, non-gravitational accelerations sensed by the IMU's are incorporated into the state vector in the SUPER_G state propagation algorithm when above a pre-set threshold. For Orbiter coasting flight or target state vector propagation, the accelerations are always modeled in the SUPER_G algorithm.

A. Detailed Requirements.-

The SUPER_G subfunction shall be invoked whenever the following statement is encountered:

CALL: SUPER_G

IN LIST: GMD,GMO,DM,VM,ATM,R_IN,V_IN,T_IN,T_FIN,DT_FILT,
DV_IN

OUT LIST: R_FIN,V_FIN,G_OUT

1. Upon initiation of SUPER_G, an initial total acceleration, G_INT , will be calculated by the ACCEL_ONORBIT function as:

$$G_INT = ACCEL_ONORBIT (GMD,GMO,DM,VM,ATM,R_IN,V_IN,T_IN)$$

where the function arguments are the appropriate flag settings (that is, the degree and order of the gravitational potential model, drag mode, vent mode, and attitude mode flag settings), current position vector, current velocity vector, and previous time.

2. Next the position vector is advanced using the current position and velocity vectors, the time interval DT_FILT , initial acceleration vector G_INT calculated in the previous step, and the value of DV_FILT :

$$R_FIN = R_IN + DT_FILT (V_IN + .5 (DV_IN + DT_FILT G_INT))$$

3. Find a new value of the total acceleration vector, based on the advanced position vector, velocity vector, and time tag:

$$G_OUT = ACCEL_ONORBIT (GMD,GMO,DM,VM,ATM,R_FIN,V_IN,T_FIN)$$

4. The vehicle velocity vector is corrected using an average total acceleration difference.

$$V_FIN = V_IN + DV_IN + .5 DT_FILT (G_INT + G_OUT)$$

5. Finally, the vehicle position vector is corrected by:

$$\underline{R}_{FIN} = \underline{R}_{FIN} + ((\underline{G}_{OUT} - \underline{G}_{INT}) DT_{FILT}^2)/6.$$

The velocity and position vectors calculated in steps 4 and 5 constitute the required propagated state.

- B. Interface Requirements. - The input and output required for the SUPER_G subfunction are listed in table 4.2.4.1. Required inputs for use of the ACCEL_ONORBIT function are given in section 4.2.4.1.1.
- C. Processing Requirements. - The SUPER_G subfunction is called by the following:

ONORBIT_REND_R_V_STATE_PROP

- D. Constraints. - The SUPER_G subroutine will be called to integrate the Orbiter and target state vectors during coasting and powered flight.
- E. Supplementary Information. - A suggested implementation of the SUPER_G subroutine, in the form of a detailed flowchart, is presented in Appendix B under

SUPER_G

4.2.4.1.1 Acceleration models (ACCEL_ONORBIT).- During orbital operations, models to account for gravitational, vent and thrust, and vehicle aerodynamic drag accelerations shall be available. These models are to be used in the Orbiter state vector propagation whenever the IMU sensed acceleration magnitude is below a given threshold level. When the sensed acceleration magnitude is above the threshold level, the gravitational acceleration model only will be used. In the Orbiter state prediction mode, only the gravitational and drag acceleration models may be used. During propagation or prediction of a target vehicle state, the gravitational and drag acceleration models may be used. Additionally, during the target state propagation mode, capability exists to incorporate the unmodeled acceleration biases as determined by the Kalman filter in REND_NAV_FILTER.

A. Detailed Requirements.- This function is activated whenever the statement ACCEL_ONORBIT (GMD,GMO,DM,VM,ATM,R,V,T) is encountered,

where:

GMD	input degree of Earth gravitational potential model (ACCEL_EARTH_GRAV)
GMO	input order of Earth gravitational potential model (ACCEL_EARTH_GRAV)
DM	flag indicating use (1) or non-use (0) of vehicle drag acceleration model (ACCEL_ONORBIT_DRAG)
VM	flag indicating use (1) or non-use (0) of vent and thrust model (ACCEL_ONORBIT_VENT_AND_THRUST)
ATM	attitude mode flag (used when DM and/or VM are set to 1.)
<u>R</u>	position vector of vehicle in M50 coordinates
<u>V</u>	velocity vector of vehicle in M50 coordinates
T	position and velocity vectors time tag

The following steps will be performed (in the order indicated) whenever the ACCEL_ONORBIT function is activated.

1. The values of G, the gravitational acceleration due to the Earth's non-spherical shape, D, the drag model acceleration vector, and VENT, the acceleration due to vent and thrusting shall be initially nulled.

G = 0.
D = 0.
VENT = 0.

The current Earth fixed to M50 transformation FIFTY will be constructed.

$$\text{FIFTY} = \text{EARTH_FIXED_TO_M50_COORD}(T)$$

Here, the EARTH_FIXED_TO_M50_COORD function is defined in section 4.10.2.

Next the input M50 position vector will be transformed to Earth fixed coordinates.

$$\underline{R_EF} = \text{FIFTY}^T \underline{R}$$

Components of the Earth fixed position unit vector will be determined by the following:

$$\underline{R_INV} = 1. / |\underline{R}|$$

F3

$$\underline{UR} = \underline{R_INV} \underline{R_EF}$$

The acceleration vector due to the Earth's gravitational attraction as a point mass will be determined by:

$$\underline{G_CENTRAL} = - \text{EARTH_MU} \underline{R_INV}^3 \underline{R}$$

2. Next the value of GMD shall be tested to determine if the gravitational acceleration vector due to the Earth's non-sphericity (G) shall be determined.

- a. If GMD is equal to or greater than 2, the ACCEL_EARTH_GRAV code will be executed - which is a model formulated using S. Pines' spherical harmonics development.

- (1) The following variables are to be set up to serve as starting values for recursive relations used in the Pines formulation:

$$\text{RO_ZERO} = \text{EARTH_RADIUS_GRAV} \underline{R_INV}$$

$$\text{RO_N} = \text{RO_ZERO} \text{EARTH_MU} \underline{R_INV}^2$$

$$\text{A}_{1,2} = 3. \text{UR}_3$$

$$\text{A}_{2,2} = 3.$$

$$\text{L} = 1$$

F3 This equation shall be protected against division by zero (Reference 3.6-3).

AUXILIARY = 0.

ZETA_REAL₁ = 1.

ZETA_IMAG₁ = 0.

A is a two-column array used for temporary storage of Legendre polynomials and derived Legendre functions (which are latitude-dependent terms), and R0 N is the distance-related term. AUXILIARY is an intermediate scalar variable.

- (2) Recursive calculations shall then proceed, using as many components of the one-column arrays ZETA_REAL and ZETA_IMAG as required to account for the effects of tesseral harmonics. ZETA_REAL and ZETA_IMAG are the only terms that depend on the vehicle's longitude.

Do for I = 1 to GMD:

ZETA_REAL_{I+1} = UR₁ ZETA_REAL_I - UR₂ ZETA_IMAG_I

ZETA_IMAG_{I+1} = UR₁ ZETA_IMAG_I + UR₂ ZETA_REAL_I

- (3) The derived Legendre functions shall then be obtained by means of recursion formulas, multiplied by appropriate combinations of tesseral harmonics (Legendre polynomials shall be multiplied by zonal harmonics coefficients), and stored as certain auxiliary variables F1, F2, F3, and F4.

Do for N = 2 to GMD the following three steps:

- AN+1,1 = 0.
AN+1,2 = (2. N + 1.) AN,2
AN,1 = AN,2
AN,2 = UR₃ AN+1,2

- Do for J = 2 to N:

AN-J+1,1 = AN-J+1,2
AN-J+1,2 = (UR₃ AN-J+2,2 - AN-J+2,1)/J

- F1 = 0.
F2 = 0.
F3 = -A_{1,1} ZONAL_N
F4 = -A_{1,2} ZONAL_N

(These account for the zonal harmonics contributions.)

- (4) If the maximum order of tesserals wanted has not been attained (i.e., if N ≤ GMD), do for N1 = 1 to N:

F1 = F1 + N1 AN1,1 (C_L ZETA_REAL_{N1} + S_L ZETA_IMAG_{N1})

$$\begin{aligned}
F2 &= F2 + N1 \ A_{N1,1} (S_L \ ZETA_REAL_{N1} - C_L \ ZETA_IMAG_{N1}) \\
DNM &= C_L \ ZETA_REAL_{N1+1} + S_L \ ZETA_IMAG_{N1+1} \\
F3 &= F3 + DNM \ A_{N1+1,1} \\
F4 &= F4 + DNM \ A_{N1+1,2} \\
L &= L + 1
\end{aligned}$$

(These take into account the contributions of the tesseral and sectorial harmonics.)

$$\begin{aligned}
(5) \quad RO_N &= RO_N \ RO_ZERO \\
G_1 &= G_1 + RO_N \ F1 \\
G_2 &= G_2 + RO_N \ F2 \\
G_3 &= G_3 + RO_N \ F3 \\
AUXILIARY &= AUXILIARY + RO_N \ F4
\end{aligned}$$

(These equations multiply the sum of zonal and tesseral effects by appropriate distance-related factors, store the results as components of the acceleration vector G, and prepare for final computation by obtaining the intermediate scalar variable AUXILIARY, which accounts for an additional effect proportional to the unit radius vector UR).

- b. Once these calculations have been completed ($N = GMD$) and stored, the Earth-fixed acceleration vector shall be obtained and rotated to the M50 coordinate system.

$$\underline{G} = \underline{G} - AUXILIARY \ \underline{UR}$$

$$\underline{G} = FIFTY \ \underline{G}$$

This is the gravitational acceleration vector needed for equations of motion of the Shuttle. Values of GMD and of GMD may be set by the user independently. However, it is necessary that $GMD \leq GMD$. A maximum value of 4 for GMD shall be used, which will make the array ZONAL have 4 components, the arrays C and S have 9 components each, ZETA_REAL and ZETA_IMAG have 5 each, and A has a maximum dimension of 5 by 2.

Terms shown in Earth's gravity calculations as C_L and S_L are usually represented by $C_{n,m}$ and $S_{n,m}$, respectively, but were renumbered for single subscript utilization; the terms called ZONAL_N correspond to $J_N = -C_{N,0}$.

The S. Pines formulation of gravitational potential may be found, in condensed form, in the paper "Uniform Representation of the Gravitational Potential and its Derivatives," AIAA Journal, Vol. 11, No. 11, November 1973. In expanded form, and with an earlier draft of the computer program herein presented, it is contained in MDC Report W0013, NASA CR 14/478, of 9 February 1976, Pines' Nonsingular Gravitational Potential: Derivation, Description and Implementation.

3. Next a test will be performed to determine if vent and thrust accelerations are to be modeled. It should be noted that the vent and thrust acceleration model is used only during state propagation (i.e., this model is not used for Orbiter or target vehicle state prediction).

```

!
! VM = 1
!

```

- a. If VM is equal to 1, vent and thrust accelerations are to be modeled for use during Orbiter or target vehicle propagations. The ACCEL_ONORBIT_VENT_AND_THRUST CODE will be executed as follows:

- (1) A check of the ATM flag will be made to determine if the modeled vent and thrust acceleration will apply to the Orbiter state propagation (ATM = 0), or target vehicle propagation (ATM = 2).

```

!
! ATM = 2
!

```

- If ATM is equal to 2, the vent and thrust acceleration is for the target vehicle. A check of the SHUTTLE_FILTER_FLAG will be made to determine if the unmodeled acceleration bias (UNMOD_ACC_BIAS) applies to the Orbiter (SHUTTLE_FILTER_FLAG = ON), or the target vehicle (SHUTTLE_FILTER_FLAG = OFF).

```

!
! SHUTTLE_FILTER_FLAG = OFF
!

```

If the Shuttle filter flag is OFF, the target vehicle vent and thrust vector (VENT) will be set equal to the unmodeled acceleration bias; otherwise the value of VENT will remain at its initialized value. The value of UNMOD_ACC_BIAS is determined in the Onorbit/Rendezvous Navigation principal function by the Kalman filter. The bias acceleration is applicable to either the Shuttle or target vehicle as indicated by setting of the SHUTTLE_FILTER_FLAG as mentioned above.

- If the value of ATM does not equal 2 in step 3a(1), the vent and thrust modeled acceleration will be for the Orbiter. The value of the SHUTTLE_FILTER_FLAG will next be checked

```

!
! SHUTTLE_FILTER_FLAG
!   = ON
!

```

and if on, the vent and thrust acceleration vector VENT is set equal to UNMOD_ACC_BIAS.

VENT=UNMOD_ACC_BIAS

- (2) The value of time (T) is tested to determine if it lies within the vent and thrust model action time span as specified by the values of TFON and TFOFF,

```

! T ≥ TFON
! and
! T < TFOFF

```

and if so, a body contact force vector (VFORCE) and the current Orbiter mass (NAV_CURR_ORB_MASS) will be used to construct the Orbiter venting and acceleration vector. A multiplication by M_BODYM50 transforms the vector from body to M50 coordinates. This acceleration vector is then added to VENT.

VENT = VENT + M_BODYM50 (VFORCE/NAV_CURR_ORB_MASS) F3

- The value VENT, the Orbiter vent and thrust modeled acceleration vector, is stored as VENT_SS to be available for downlist.

4. After the ACCEL_ONORBIT_VENT_AND_THRUST logic has been satisfied, the drag model flag (DM) shall be tested

```

! DM = 1

```

and if true (DM = 1), the vehicle drag acceleration vector shall be determined.

- a. The first step to be performed in the vehicle drag computational flow will be to exercise the SOLAR_EPHEM subfunction by the following:

CALL: SOLAR_EPHEM

INLIST: T

OUTLIST: SDEC,CDEC1,COS_SOL_RA,SIN_SOL_RA

F3 This equation shall be protected against division by zero (Reference 3.6-3).

Where:

CDEC1 = cosine of the solar declination
 COS_SOL_RA = cosine of the solar right ascension
 SDEC = sine of the solar declination
 SIN_SOL_RA = sine of the solar right ascension
 T = time of desired computation

- b. Next the ONORBIT_DENSITY code will be exercised to provide the atmospheric density value associated with the vehicle position. This section of code is initiated with determination of the vehicle altitude (ALT) above the reference ellipsoid through use of the H_ELLIPSOID function (see section 4.2.4.1.1.1).

$$ALT = H_ELLIPSOID(R)$$

where R is the vehicle M50 position vector.

- (1) The next series of expressions will be performed to determine GDI, one of the Babb-Mueller atmospheric density diurnal factors.

CDEC1 = CDEC1 R_INV
 SDEC = SDEC R_INV R3
 CSFST = R1 COS_SOL_RA COS_LAG
 CSSND = R1 SIN_SOL_RA SIN_LAG
 SIFST = R2 SIN_SOL_RA COS_LAG
 SSND = R2 COS_SOL_RA SIN_LAG
 COS_PSI = SDEC + CDEC1 (CSFST - CSSND + SIFST + SSND)
 GDI = ((1.0 + COS_PSI)/2.0)^{GDIE}

where COS_LAG, SIN_LAG and GDIE are design dependent parameters (see section 4.7).

- (2) A check of the vehicle altitude above the reference ellipsoid (ALT) will be made to see if it is greater than ALT_L (the Babb-Mueller density layer altitude).

```

!
! ALT > ALT_L
!

```

If the statement is true, the layering index integer K will be set to 2; otherwise K will be set to 1.

- (3) The night-time vertical density profile factor (AFH) will be determined

$$AFH = ABM_{1,K} + ABM_{2,K} ALT + ABM_{3,K} / ALT$$

F3

where ABM_1 TO $3, K$ are mission dependent calibration coefficients (see section 4.7). The diurnal density effect will be determined next.

$$BFH = (BM_1 + BM_2 ALT + BM_3/ALT) GDI \quad F3$$

The BM_1 TO 3 are mission dependent calibration coefficients (see section 4.7). A seasonal-latitudinal term will be determined as follows,

$$CBM1 = ALT - C_DENSEA$$

$$CBM1 = (CBD1(R_INV)^2 \text{ ABS } (R_3)R_3)CBM1 \text{ EXP } (CBD2 CBM1)$$

C_DENSEA , $CBD1$ and $CBD2$ are design dependent parameters (see section 4.7).

- (4) The atmospheric density will now be determined as

$$RHO = RREF \text{ EXP } (AFH + BFH + CBM1 CBM2)$$

Here $RREF$ is a design dependent parameter and $CBM2$ is a seasonal-latitudinal mission dependent parameter (see section 4.7).

- c. Next the $ACCEL_ONORBIT_DRAG$ code will be executed using the atmospheric density value of (RHO) previously determined. The code will begin with calculation of the vehicle velocity vector in Earth-relative M50 coordinates as determined by

$$\underline{V_R} = \underline{V_REL} (\underline{V}, \underline{R})$$

where $\underline{V_REL} (\underline{V}, \underline{R})$ is the Earth relative velocity function (see section 4.2.4.1.1.2), and $\underline{V}, \underline{R}$ are the vehicle velocity and position vectors in M50 coordinates.

- (1) A test to determine if ATM is greater than 0 is performed:

- If ATM is greater than 0, a second test will be performed to determine if ATM is equal to 1.

F3 This equation shall be protected against division by zero (Reference 3.6-3).

If ATM is equal to 1, the drag computation will be for Orbiter state prediction and will use the following configuration parameters:

VEH_MASS = PRED_ORB_MASS
 CD = PRED_ORB_CD
 AREA = PRED_ORB_AREA

The values of PRED_ORB_MASS, PRED_ORB_CD and PRED_ORB_AREA to be used will be determined by that principal function which initiates a call to the Onorbit predictor.

If in the test of ATM, ATM does not equal 1, the ensuing drag computation will be used for a target vehicle state propagation or prediction mode. The following configuration parameters will be set:

VEH_MASS = TARGET_MASS
 CD = TARGET_CD
 AREA = TARGET_AREA

Here TARGET_MASS, TARGET_CD and TARGET_AREA are mission dependent parameters (I-LOAD parameters - section 4.7).

- (2) If in the test of ATM, ATM is not greater than 0, the computation of drag will be used for Orbiter state propagation.

In the above event, VEH_MASS and AREA will be designated by:

VEH_MASS = NAV_CURR_ORB_MASS
 AREA = REF_ORB_AREA

where NAV_CURR_ORB_MASS was set by NAV_ONORBIT_RENDEZVOUS and REF_ORB_AREA is a design dependent parameter (see section 4.7).

The coefficient of drag, CD, shall be determined as follows for Orbiter state propagation.

- First, V_REL_BODY , the vehicle velocity vector relative to the atmosphere, but expressed in body coordinates, is determined as:

$$V_REL_BODY = (M_BODYM50)^T V_R$$

where M_BODYM50 is the transformation matrix of body to M50 coordinates and V_R has been determined in c.

- Next the square of the sine of the vehicle angle of attack (SA) will be determined as:

$$SA = (V_REL_BODY_3)^2 / (V_REL_BODY_1^2 + V_REL_BODY_3^2) \quad F3$$

The sine of the vehicle sideslip angle, SB, will be determined by the following:

$$SB = |V_REL_BODY_2| / |V_R| \quad F3$$

The sine of twice the sideslip angle S2B will be determined by:

$$S2B = 2 \cdot SB \cdot \text{SQRT} (1 - SB^2) \quad F4$$

- The Orbiter coefficient of drag CD may now be determined as:

$$CD = ((CDF + CDN \cdot SA \cdot \text{EXP_SHAPE_FACTOR}) \cdot (1 - SB) + CDS \cdot SB + CDA \cdot S2B \cdot SA) \cdot KFACTOR$$

The vehicle configuration constants CDF, CDN, EXP_SHAPE_FACTOR, CDS and CDA are design dependent parameters (see section 4.7). KFACTOR is the drag coefficient adjustment factor and is mission dependent (see section 4.7) and included as an uplink parameter (see section 4.9). The parameter KFACTOR is included to allow adjustments to the vehicle drag coefficient due to configuration parameter uncertainties, atmospheric density model deviations or other causes during Orbiter state propagation.

- (3) After vehicle parameters VEH_MASS, AREA and CD have been determined by one of the logic paths of 4c(1) or of 4c(2) as dictated by the value of the ATM flag, a vehicle drag acceleration vector D in M50 coordinates will be determined by:

$$\underline{D} = -0.5 \cdot CD \cdot \rho \cdot AREA \cdot |V_R| \cdot V_R / VEH_MASS \quad F3$$

- (4) If the drag acceleration D is being computed for the Orbiter during state propagation, ATM=0, it shall be stored in D_SS for downlist. ALT, the vehicle altitude above the Earth's reference ellipsoid, will be also saved in ALT_SS for downlist.

F3 This equation shall be protected against division by zero (Reference 3.6-3).
 F4 This equation shall be protected against square roots of a negative number (Reference 3.6-4).

5. Finally, the acceleration values G, D and VENT determined by the non-spherical Earth gravitational, vehicle drag, and vent and thrust models, respectively, will be combined with the value of point mass Earth gravitational acceleration (G_CENTRAL) to result in the final ACCEL_ONORBIT function M50 output vector.

$$\text{ACCEL_ONORBIT} = \text{G_CENTRAL} + \text{G} + \text{D} + \text{VENT}$$

- B. Interface Requirements.-- The input and output data are shown in table 4.2.4.1.1. It should be noted that ACCEL_ONORBIT is treated as a function subprogram; that is, the computed value of the acceleration vector will be returned and occupy the position of the function name.
- C. Processing Requirements.-- This function subprogram shall be performed each time the function name is encountered with suitable expressions for arguments such as:

ACCEL_ONORBIT (GMD,GMO,DM,VM,ATM,R,V,T)

The ACCEL_ONORBIT function is used by the following:

SUPER_G
ONORBIT_SV_INTERP
REND_COV_INIT
PINES_METHOD
AVERAGE_G_INTEGRATOR

- D. Constraints.-- The currently functioning propagator and a predictor may need different acceleration models at the same time. It is therefore necessary that execution of the acceleration calculations be protected from interruption by other users.
- E. Supplementary Information.-- A suggested implementation of the ACCEL_ONORBIT in the form of detailed flowcharts may be found in Appendix B under the names:

ACCEL_ONORBIT_FUNCTION
ACCEL_EARTH_GRAV_CODE
ACCEL_ONORBIT_VENT_AND_THRUST_CODE
SOLAR_EPHEM
ONORBIT_DENSITY_CODE
H_ELLIPSOID_FUNCTION
ACCEL_ONORBIT_DRAG_CODE
V_REL_FUNCTION

and the following from Appendix C:

†Only the value of the function is passed

4.2.4.1.1.1. Altitude above the reference ellipsoid (H_ELLIPSOID): Altitude above the Earth's reference ellipsoid in M50 coordinates will be determined using the H_ELLIPSOID function.

- A. Detailed Requirements.- Altitude above the Earth's reference ellipsoid will be calculated each time the statement H_ELLIPSOID (R) is encountered. Here R is the vehicle M50 position vector. The value of altitude above the Earth's reference ellipsoid will be determined using the following:

$$H_ELLIPSOID(R) =$$

$$|R| - \frac{(1 - ELLIPT) \text{ EARTH_RADIUS_EQUATOR}}{\sqrt{1 + ((1-ELLIPT)^2 - 1) (1 - (\text{UNIT}(R) \cdot \text{EARTH_POLE})^2)}} \quad \begin{matrix} F3 \\ F4 \end{matrix}$$

where ELLIPT, EARTH_RADIUS_EQUATOR, and EARTH_POLE are constants defined in section 4.7 (Initialization parameters).

- B. Interface Requirements.- The input and output data are shown in table 4.2.4.1.1.1. It should be noted that only the value of H_ELLIPSOID is passed.
- C. Processing Requirements.- The H_ELLIPSOID function will be processed each time the function name is encountered with a suitable expression for the argument such as: H_ELLIPSOID (R). The H_ELLIPSOID function is used by the following.

ACCEL_ONORBIT

- D. Constraints.- None
- E. Supplementary Information.- A suggested implementation of the H_ELLIPSOID function in the form of a detailed flowchart may be found in Appendix B under the name:

H_ELLIPSOID FUNCTION

F3 This equation shall be protected against division by zero (Reference 3.6-3).
 F4 This equation shall be protected against square roots of a negative number (Reference 3.6-4).

4.2.4.1.1.2 Earth relative velocity computation (V_{REL}): The velocity vector relative to the Earth but expressed in M50 coordinates will be determined using the V_{REL} function.

- A. Detailed Requirements.-- The function is activated whenever the statement $V_{REL}(V,R)$ is encountered. The function arguments are the M50 velocity vector (V) and M50 position vector (R). The vector V_{REL} is determined by the following:

$$V_{REL}(V,R) = V - EARTH_RATE (EARTH_POLE \times R)$$

where $EARTH_RATE$ and $EARTH_POLE$ are constants defined in section 4.7 (Initialization parameters).

- B. Interface Requirements.-- The input and output data are shown in table 4.2.4.1.1.2. It should be noted that only the value of V_{REL} is passed.
- C. Processing Requirements.-- The V_{REL} function will be processed each time the function name is encountered with a suitable expression for the arguments such as $V_{REL}(V,R)$. The V_{REL} function is used by $ACCEL_ONORBIT$
- D. Constraints.-- None
- E. Supplementary Information.-- A suggested implementation of the V_{REL} function in the form of a detailed flowchart may be found in Appendix B under the name:

4.2.4.1.1.3 Solar ephemeris model (SOLAR_EPHEM)

Output from the solar ephemeris model will provide sine and cosine functions of the solar right ascension and declination. These outputs are to be used in the acceleration models (ACCEL_ONORBIT) for determination of atmospheric density and in position and velocity state propagation (ONORBIT_REND_R_V_STATE_PROP) for computation of a unit vector from earth center to the center of the sun in M50 coordinates to be available for the universal pointing processing principal function.

A. Detailed Requirements.

The solar ephemeris subfunction shall be invoked whenever the following statement is encountered:

CALL: SOLAR_EPHEM

IN LIST: T

OUT LIST: SDEC,CDEC1,COS_SOL_RA,SIN_SOL_RA

where:

CDEC1 = cosine of the solar declination
 COS_SOL_RA = cosine of the solar right ascension
 SDEC = sine of the solar declination
 SIN_SOL_RA = sine of the solar right ascension
 T = time of desired computation

The SOLAR_EPHEM subfunction will initiate the following calculations in the indicated order:

1. The longitude of the Sun in M50 coordinates, LOS, will be determined as

$$LOS = LOS_ZERO + T LOS_R - LOC \sin(T \ OMEG_C + PHASE_C). \quad F9$$

Here, LOS_ZERO, LOS_R, LOS, OMEG_C and PHASE_C are design dependent parameters (see section 4.7).

2. The sine and cosine of the solar declination SDEC and CDEC1 are calculated by

$$\begin{aligned} SDEC &= LCK3 \sin(LOS) & F9 \\ CDEC1 &= \sqrt{1 - SDEC^2} & F4 \end{aligned}$$

F4 This operation shall be protected against square roots of a negative number (Reference 3.6-4).

F9 This equation shall be protected against return value of sine or cosine with magnitude greater than unity (Reference 3.6-9).

3. The cosine and sine of the solar right ascension are determined by

$$\begin{aligned}\text{COS_SOL_RA} &= \text{COS}(\text{LOS})/\text{CDEC1} & \text{F9, F3} \\ \text{SIN_SOL_RA} &= \text{LOS1 SIN}(\text{LOS})/\text{CDEC1} & \text{F3}\end{aligned}$$

LOS1 and LOS3 are design dependent parameters (see section 4.7).

- B. Interface Requirements. The input and output required of the SOLAR_EPHEM subfunction are listed in table 4.2.4.1.1.3.
- C. Processing Requirements. The SOLAR_EPHEM subfunction shall be called by the acceleration subfunction program ACCEL_ONORBIT and the ONORBIT_REND_R_V_STATE_PROP.
- D. Constraints. None
- E. Supplementary Information. A suggested implementation of the SOLAR_EPHEM function in the form of a detailed flowchart may be found in Appendix B under the name:

SOLAR_EPHEM

F3 This equation shall be protected against division by zero (Reference 3.6-3).

F9 This equation shall be protected against return value of sine or cosine with magnitude greater than unity (Reference 3.6-9).

4.2.5 Unmodeled Acceleration State and Covariance Matrix Propagation (REND_BIAS_AND_COV_PROP)

The unmodeled acceleration state and covariance matrix propagation subfunction will be executed only during the rendezvous navigation phase and will be scheduled by the Onorbit/Rendezvous control subfunction, ONORBIT_RENDEZVOUS_NAV, at an N_CYCLE multiple of the state propagation rate. The rate at which this subfunction is executed will be called the filter subcycle rate. The following tasks will be performed during each execution.

- If IMU sensed accelerations were used at any time during the previous covariance propagation interval but are not used at all during the current propagation interval, or if IMU sensed accelerations were not used at all during the previous covariance propagation interval but are used at some time during the current propagation interval, then the unmodeled acceleration bias vector as well as the unmodeled acceleration portions of the covariance matrix are reinitialized.
- The unmodeled acceleration bias vector will be propagated to current time as an exponentially correlated random variable (ECRV).
- A 13-by-13 covariance matrix, E, shall be propagated to current time by using a state transition matrix.
- Additive process noise will be incorporated into the covariance matrix to account for unmodeled state and dynamic errors.
- Finally, a flag (NAV_MEAS) is set to ON, to allow measurement incorporation, only if the magnitude of the IMU sensed acceleration vector is below a design dependent threshold.

The 13-by-13 state transition matrix ϕ is mathematically defined as the partial of the current state with respect to the previous state. For propagation of the filter vehicle covariance matrix, ϕ will be formulated as shown below.

$$\phi = \begin{bmatrix} \text{PHI}_{6 \times 9} & \begin{matrix} 0_{3 \times 4} \\ 0_{3 \times 4} \end{matrix} \\ \begin{matrix} 0_{3 \times 6} \\ 0_{4 \times 6} \end{matrix} & \begin{matrix} \text{PHI_UNMOD_ACC} & 0_{3 \times 4} \\ 0_{4 \times 3} & \text{PHI_BIAS} \end{matrix} \end{bmatrix}$$

State Transition Matrix Composition

The submatrices Φ_1 to 9, 10 to 13, Φ_7 to 9, 1 to 6, and Φ_{10} to 13, 1 to 9 are null matrices.

The state noise matrix, NOISE, shall be formulated as shown below. The matrix is to be used to account for unmodeled state errors, unmodeled acceleration errors, and sensor bias errors.

$$\text{NOISE} = \begin{bmatrix} S_{6 \times 6} & 0_{6 \times 3} & 0_{6 \times 4} \\ 0_{3 \times 6} & S_{\text{UNMOD_ACC}} & 0_{3 \times 4} \\ 0_{4 \times 6} & 0_{4 \times 3} & S_{\text{BIAS}} \end{bmatrix}$$

State Noise Matrix Composition

The submatrices NOISE 1 to 6, 7 to 13, NOISE 7 to 9, 10 to 13, NOISE 7 to 9, 1 to 6, and NOISE 10 to 13, 1 to 9 are null matrices.

The above formulations for both the state transition and the state noise transition matrices were made for clarity and code efficiency.

The unmodeled acceleration state and covariance matrix propagation subfunction will also propagate the unmodeled acceleration bias states as ECRV's.

A. Detailed Requirements.- The following steps shall be performed:

1. If there has been a change in the value of the COV_PWRD_FLT flag (COV_PWRD_FLT = ON indicates that the sensed delta velocity has exceeded a threshold value since the previous covariance propagation cycle) since the last filter cycle, then reinitialize the unmodeled acceleration states.

a. EXECUTE: UNMOD_ACC_REINIT CODE

- (1) Zero the unmodeled acceleration state portions of the covariance matrix.

$$E_{7 \text{ to } 9, 1 \text{ to } 13} = 0.0$$

$$E_{1 \text{ to } 13, 7 \text{ to } 9} = 0.0$$

- (2) Set up the time constants and variances as a function of the COV_PWRD_FLT flag.

- If the sensed delta velocity is above the threshold

(COV_PWRD_FLT = ON), then
 TAU_UNMOD_ACC_COV = TAU_U_A_PWRD_FLT
 VAR_UNMOD_ACC = VAR_U_A_PWRD_FLT
 COV_ACCEL_UVW_INIT = COV_U_A_PWRD_FLT

- If the sensed delta velocity is less than or equal to the threshold (COV_PWRD_FLT = OFF), then

TAU_UNMOD_ACC_COV = TAU_U_A_COAST
 VAR_UNMOD_ACC = VAR_U_A_COAST
 COV_ACCEL_UVW_INIT = COV_U_A_COAST

- (3) Reinitialize the unmodeled acceleration biases and the unmodeled acceleration slots of the covariance matrix.

- If the Shuttle is the filter vehicle (SHUTTLE_FILTER_FLAG = ON), then

CALL: U_A_BIAS_AND_COVINIT
 IN LIST: R_FILT, V_FILT

(Refer to section 4.2.5.1 for detailed requirements.)

If the target is the filter vehicle (SHUTTLE_FILTER_FLAG = OFF), then

CALL: U_A_BIAS_AND_COVINIT
 IN LIST: R_TV, V_TV

(Refer to section 4.2.5.1 for detailed requirements.)

- (4) Save the last value of COV_PWRD_FLT.
 COV_PWRD_FLT_LAST = COV_PWRD_FLT

2. Compute the change in time since the last covariance propagation subcycle

$$DT_COV = T_CURRENT_FILT - T_COV_LAST$$

where T_COV_LAST is the time of the last covariance matrix propagation subcycle. Also TOT_ACC, the total acceleration vector for the Shuttle, shall be calculated for use in the state vector interpolation routine

$$TOT_ACC = \underline{G_NEW} + \underline{DV_COV}/DT_COV \quad F3$$

where DV_COV is the total accumulated sensed delta velocity since the time of the last covariance matrix propagation subcycle and G_NEW is the Shuttle acceleration vector.

F3 This equation shall be protected against division by zero (Reference 3.6-3).

3. The SHUTTLE_FILTER_FLAG is tested to determine which vehicle is used to calculate the 6-by-6 submatrix, PHI₁ to 6, 1 to 6 (Φ₁ to 6, 1 to 6), composed of the filter vehicle position and velocity portion of the total state transition matrix. This submatrix is calculated by calling the mean conic partials subfunction (described in section 4.2.5.2).

a. If the Shuttle is the filter vehicle

(SHUTTLE_FILTER_FLAG = ON)

- (1) CALL: MEAN_CONIC_PARTIAL_TRANSITION_MATRIX_6x6

IN LIST: R_LAST, V_LAST, TOT_ACC_LAST, R_FILT, V_FILT,
TOT_ACC, DT_COV

OUT LIST: PHI₁ to 6, 1 to 6

- (2) Compute a UVW to mean of 1950 transformation matrix for the Shuttle for use in the state noise formulation.

MAT = UVW_TO_M50 (R_FILT, V_FILT)

(Refer to section 4.10.10 for a detailed description.)

The current inertial Orbiter vehicle acceleration shall be saved for the next filter subcycle

TOT_ACC_LAST = TOT_ACC

b. If the target is the filter vehicle

(SHUTTLE_FILTER_FLAG = OFF)

- (1) CALL: MEAN_CONIC_PARTIAL_TRANSITION_MATRIX_6x6

IN LIST: R_TV_LAST, V_TV_LAST, G_TV_LAST, R_TV, V_TV,
G_TV, DT_COV

OUT LIST: PHI₁ to 6, 1 to 6

- (2) Compute a UVW to mean of 1950 transformation matrix for the target vehicle for use in the state noise formulation.

MAT = UVW_TO_M50 (R_TV, V_TV)

(Refer to section 4.10.10 for a detailed description.)

The current inertial target vehicle acceleration vector shall be saved for the next filter subcycle.

G_TV_LAST = G_TV

4. Calculate a scalar, PHI_UNMOD_ACC , which will be stored into the diagonal elements of the unmodeled acceleration bias portion of the state transition matrix (ϕ 7 to 9, 7 to 9)

$$\text{PHI_UNMOD_ACC} = \exp(-\text{DT_COV}/\text{TAU_UNMOD_ACC_COV}) \quad \text{F2}$$

A value used to compute the remainder of the PHI matrix is also calculated.

$$\text{DIAG} = \text{TAU_UNMOD_ACC_COV} (1. - \text{PHI_UNMOD_ACC})$$

where DIAG is in mean of 1950 coordinates.

5. The unmodeled acceleration bias states shall be propagated as ECRV's as follows:

$$\text{UNMOD_ACC_BIAS} = \exp(-\text{DT_COV}/\text{TAU_UNMOD_ACC_STATE} \cdot \text{UNMOD_ACC_BIAS}) \quad \text{F2}$$

6. Calculate a 3-by-3 diagonal matrix S_UNMOD_ACC (NOISE_{7 to 9, 7 to 9}) composed of the unmodeled acceleration errors where

$$\begin{aligned} \text{S_UNMOD_ACC}_{I,I} &= \text{VAR_UNMOD_ACC}_I (1. - \text{PHI_UNMOD_ACC}^2) \quad (\text{for } I = 1 \text{ to } 3) \\ \text{S_UNMOD_ACC} &= \text{MAT } \text{S_UNMOD_ACC} \text{ MAT}^T \end{aligned}$$

and MAT is the UVW to mean of 1950 coordinate transformation matrix for the filter vehicle.

7. Calculate a 6-by-3 submatrix, $\text{PHI}_{1 \text{ to } 6, 7 \text{ to } 9}$ (ϕ 1 to 6, 7 to 9), composed of two 3-by-3 diagonal submatrices that correlate the position and velocity with the estimated unmodeled accelerations where

$$\begin{aligned} \text{PHI}_{1+3, I+6} &= \text{DIAG} \\ \text{PHI}_{I, I+6} &= \text{TAU_UNMOD_ACC_COV} (\text{DT_COV} - \text{DIAG}) \end{aligned}$$

(for $I = 1$ to 3)

8. Calculate a vector, PHI_BIAS , which will be stored into the diagonal elements of the sensor bias portion of the total state transition matrix (ϕ 10 to 13, 10 to 13).

$$\text{PHI_BIAS}_I = \exp(-\text{DT_COV}/\text{TAU_SENS}_I)$$

(for $I = 1$ to 4)

F2

F2 This equation shall be protected against floating point underflow (Ref. 3.6-2).

9. Calculate a vector, S_BIAS , which will be stored into the diagonal elements of the sensor bias portion of the total state noise matrix (NOISE₁₀ to 13, 10 to 13)

$$S_BIAS_I = VAR_SENS_I (1. - PHI_BIAS_I^2)$$

(for I = 1 to 4)

10. Propagate the covariance matrix

EXECUTE: PHI_E_PHI_TRANSPOSE CODE

- a. $E \Phi^T$ $\left\{ \begin{array}{l} TEMP_1 \text{ to } 13, 1 \text{ to } 6 = E_1 \text{ to } 13, 1 \text{ to } 9 PHI^T \\ TEMP_{J,I+6} = E_{J,I+6} PHI_UNMOD_ACC \text{ (for } I=1 \text{ to } 3, J=1 \text{ to } 13) \\ TEMP_{J,K+9} = E_{J,K+9} PHI_BIAS_K \text{ (for } J=1 \text{ to } 13, K=1 \text{ to } 4) \end{array} \right.$
- b. $\Phi E \Phi^T$ $\left\{ \begin{array}{l} E_1 \text{ to } 6, 1 \text{ to } 13 = PHI TEMP_1 \text{ to } 9, 1 \text{ to } 13 \\ E_{I+6,J} = PHI_UNMOD_ACC TEMP_{I+6,J} \text{ (for } I=1 \text{ to } 3, J=1 \text{ to } 13) \\ E_{K+9,J} = PHI_BIAS_K TEMP_{K+9,J} \text{ (for } J=1 \text{ to } 13, K=1 \text{ to } 4) \end{array} \right.$
- c. $\Phi E \Phi^T + NOISE$ $\left\{ \begin{array}{l} E_{7 \text{ to } 9, 7 \text{ to } 9} = E_{7 \text{ to } 9, 7 \text{ to } 9} + S_UNMOD_ACC \\ E_{K+9,K+9} = E_{K+9,K+9} + S_BIAS_K \text{ (for } K=1 \text{ to } 4) \end{array} \right.$
- d. If IMU sensed acceleration data have been used (COV_PWRD_FLT=ON) since the last covariance matrix propagation subcycle, then

- (1) Reset the COV_PWRD_FLT flag

COV_PWRD_FLT = OFF and

EXECUTE: PWRD_FLT_NOISE CODE

- Calculate a 6-by-6 matrix S (NOISE₁ to 6, 1 to 6) composed of misalignment errors:

$$S_{4,4} = DV_COV_3^2 + DV_COV_2^2$$

$$S_{5,5} = DV_COV_1^2 + DV_COV_3^2$$

$$S_{6,6} = DV_COV_1^2 + DV_COV_2^2$$

$$S_{4,5} = -DV_COV_1 DV_COV_2$$

$$S_{4,6} = -DV_COV_1 DV_COV_3$$

$$S_{5,6} = -DV_COV_2 \ DV_COV_3$$

$$S_{6,5} = S_{5,6}$$

$$S_{6,4} = S_{4,6}$$

$$S_{5,4} = S_{4,5}$$

$$S_{4 \text{ to } 6, 4 \text{ to } 6} = (VAR_IMU_ALIGN) \ S_{4 \text{ to } 6, 4 \text{ to } 6}$$

$$S_{1 \text{ to } 3, 4 \text{ to } 6} = 0.5 (DT_COV) \ S_{4 \text{ to } 6, 4 \text{ to } 6}$$

$$S_{1 \text{ to } 3, 1 \text{ to } 3} = 0.5 (DT_COV) \ S_{1 \text{ to } 3, 4 \text{ to } 6}$$

- (2) Add the powered flight noise to the covariance matrix

$$E_{1to6, 1to6} = E_{1to6, 1to6} + S$$

- e. Test the flag NOISY_NAV_MEAS to see if the sensed contact acceleration has exceeded the measurement threshold

- (1) If NOISY_NAV_MEAS = ON

- Reset NOISY_NAV_MEAS to OFF for the next covariance matrix propagation subcycle.
- Reset the measurement ACCEPT/REJECT counters. (See section 4.1.2.2.1.2)

CALL: DISPLAY_COUNT_INIT

- (2) If NOISY_NAV_MEAS = OFF

- Set the flag NAV_MEAS to ON so that the sensor measurements may be incorporated on the current filter subcycle.

11. As a final step in the covariance propagation, the entire 13-by-13 covariance matrix shall be made symmetric:

$$E_{J,I} = E_{I,J} \text{ (for } I = 1to12, J = I+1to13)$$

- B. Interface Requirements.— The input and output data are shown in table 4.2.5.
- C. Processing Requirements.— The subfunction is called by NAV_ONORBIT_RENDEZVOUS (section 4.2.1).
- D. Constraints.— Either uplinked or mission dependent data are to be used for initialization. The propagated matrix must remain symmetric.
- E. Supplementary Information.— A suggested implementation in the form of detailed flowcharts can be found in Appendix B under the following names:

4.2.5.1 Unmodeled Acceleration Bias and Covariance Initialization (U_A_BIAS_AND_COVINIT)

The initialization subfunction initializes the unmodeled acceleration bias states and the corresponding elements of the covariance matrix whenever the covariance matrix is reinitialized or whenever the unmodeled acceleration bias and covariance propagation subfunction has detected a change in the value of the flag COV_PWRD_FLT, which indicates whether the magnitude of the IMU sensed acceleration has exceeded the threshold value DA_THRESHOLD on the current covariance propagation subcycle.

- A. Detailed Requirements. This subfunction is called with the following internal variables in the IN LIST:

IN LIST: R, V

where R and V are the input position and velocity vectors of the filter vehicle in mean of 1950 coordinates.

The following steps shall be performed (in the order indicated):

1. Zero the unmodeled acceleration bias states

$$\text{UNMOD_ACC_BIAS} = 0.$$

2. Compute the UVW to mean of 1950 coordinate transformation matrix

$$\text{M_UVW_M50} = \text{UVW_TO_M50}(\text{R}, \text{V})$$

(refer to section 4.10.10 for a detailed description).

3. Initialize the unmodeled acceleration bias slots of the covariance matrix to initial UVW values and transform to mean of 1950 coordinates,

$$\text{E}_{I+6, I+6} = \text{COV_ACCEL_UVW_INIT}_I \text{ (for } I = 1 \text{ to } 3)$$

$$\text{E}_{7\text{to}9, 7\text{to}9} = \text{M_UVW_M50} \text{ E}_{7\text{to}9, 7\text{to}9} \text{ M_UVW_M50}^T$$

- B. Interface Requirements. The input and output data are shown in table 4.2.5.1.

- C. Processing Requirements. This subfunction is called by

REND_BIAS_AND_COV_PROP (section 4.2.5) and by
COVINIT_UVW (section 4.1.2.2.1.1)

- D. Constraints. Mission dependent (ILOAD) data are used for initialization.

- E. Supplementary Information. A suggested implementation in the form of a detailed flowchart may be found in Appendix B under the name of U_A_BIAS_AND_COVINIT.

4.2.5.2 Position-Velocity Submatrix of the State Transition Matrix (MEAN_CONIC_PARTIAL_TRANSITION_MATRIX_6X6)

This subfunction computes a 6 by 6 submatrix (PHI_MC) of a larger state transition matrix for use in propagating the covariance matrix. This subfunction is also invoked by the rendezvous navigation interpolation subfunction for use in calculating the partial derivative vector.

- A. Detailed Requirements. This subfunction is called with the following internal variables in the INLIST and OUTLIST:

INLIST: R_ONE, V_ONE, G_ONE, R_TWO, V_TWO, G_TWO, DELTIM

OUTLIST: PHI_MC

where

<u>R_ONE</u>	initial position vector
<u>V_ONE</u>	initial velocity vector
<u>G_ONE</u>	initial total acceleration vector
<u>R_TWO</u>	final position vector
<u>V_TWO</u>	final velocity vector
<u>G_TWO</u>	final total acceleration vector
DELTIM	time step

The following steps shall be performed (in the order indicated):

1. A formulation is used that assumes that a mean conic section may be used to describe the path taken between the initial position and velocity (R_ONE and V_ONE) at initial total acceleration (G_ONE) and the final position and velocity (R_TWO and V_TWO) at final total acceleration (G_TWO) over a time step DELTIM.

The following local variables are computed:

$$\begin{aligned}
 R_ONE_INV &= 1./|R_ONE| & F3 \\
 R_TWO_INV &= 1./|R_TWO| & F3 \\
 D_ONE &= R_ONE \cdot V_ONE \\
 D_TWO &= R_TWO \cdot V_TWO
 \end{aligned}$$

2. The ergodic semi-major axis SMA, is computed by using the average of the reciprocal of the semi-major axis derived from combination of the respective vis-viva computations at the initial and final orbital states, and is given by:

$$SMA = 1./ \left(\frac{R_ONE_INV + R_TWO_INV - (V_ONE \cdot V_ONE + V_TWO \cdot V_TWO)/(2 \cdot EARTH_MU)}{2} \right) \quad F3$$

F3 This equation shall be protected against division by zero (Reference 3.6-3).

where EARTH_MU is the Earth's gravitational constant. The Stumpff constant, C1, predicated on the mean conic semi-major axis, is computed by:

$$C1 = \text{SQRT} (SMA) / \text{SQRT_EMU}$$

F3, F4

3. The F_AND_G subfunction is then invoked to compute the F and G functions, the derivatives of F and G, as well as the auxiliary variables S0, S1, S2 and S3. These quantities are fundamental to the computation of the mean conic transition matrix.

CALL: F_AND_G

IN LIST: SMA, DELTIM, C1, R_ONE, R_ONE_INV, R_TWO_INV, V_ONE, D_ONE, D_TWO

OUT LIST: F, G, FDOT, GDOT, S0, S1, S2, S3, R_TWO, R_TWO_INV, THETA

For this case, R_TWO and R_TWO_INV are not updated since R_TWO_INV is supplied as a non-zero quantity. However, THETA, the eccentric anomaly angle, is generated as an output in any case.

4. Compute auxiliary constants:

$$FM1 = F - 1$$

$$GDM1 = GDOT - 1$$

$$S1 = C1 S1$$

$$C2 = C1^2$$

$$\text{CONST} = C2 (EARTH_MU C2 (3. S3 C1 - S1 S2) + G S2)$$

$$S2 = C2 S2$$

which represent common functionals and Stumpff series summations for circular or elliptical orbits.

5. The partial derivatives are now calculated. The equation for the partial derivatives are written algebraically for clarity, with R_0

representing R_ONE , R representing R_TWO , \dot{R}_0 representing V_ONE , \dot{R}

representing V_TWO , \ddot{R}_0 representing G_ONE , \ddot{R} representing G_TWO , r

representing F , g representing G , \dot{f} representing $FDOT$, \dot{g} representing $GDOT$ and U representing $CONST$, as well as having lower case letters

F3 This equation shall be protected against division by zero (Reference 3.6-3).

F4 This equation shall be protected against square roots of a negative number (Reference 3.6-4).

representing the scalar magnitude of the respective upper case letter vectors.

$$\begin{aligned}
 \text{PHI_MC}_1 \text{ to } 3, 1 \text{ to } 3 &= \frac{\partial R}{\partial R_0} = - \left[\frac{\dot{f} S_1 + (f-1)/r_0}{r_0} \right] R \dot{R}_0^T \\
 &\quad - \dot{f} S_2 R \dot{R}_0^T \\
 &\quad + \frac{(f-1)S_1}{r_0} \dot{R} R_0^T + (f-1) S_2 \dot{R} \dot{R}_0^T \\
 &\quad + U \dot{R} \ddot{R}_0^T + f I
 \end{aligned} \tag{F3}$$

$$\begin{aligned}
 \text{PHI_MC}_1 \text{ to } 3, 4 \text{ to } 6 &= \frac{\partial R}{\partial R_0} = - \dot{f} S_2 R R_0^T - (g-1) S_2 R \dot{R}_0^T \\
 &\quad + (f-1) S_2 \dot{R} R_0^T + g S_2 \dot{R} \dot{R}_0^T \\
 &\quad + g I - U \dot{R} \dot{R}_0^T
 \end{aligned}$$

$$\begin{aligned}
 \text{PHI_MC}_4 \text{ to } 6, 1 \text{ to } 3 &= \frac{\partial R}{\partial R_0} = - \dot{f} \left(\frac{S_0}{r r_0} + \frac{1}{r^2} + \frac{1}{r_0^2} \right) R R_0^T \\
 &\quad - \left[\frac{\dot{f} S_1 + (g-1)/r}{r} \right] R \dot{R}_0^T \\
 &\quad + \left[\frac{\dot{f} S_1 + (f-1)/r_0}{r_0} \right] \dot{R} R_0^T + \dot{f} S_2 \dot{R} \dot{R}_0^T \\
 &\quad + \dot{f} I + U \dot{R} \ddot{R}_0^T
 \end{aligned} \tag{F3}$$

F3 This equation shall be protected against division by zero (Reference 3.6-3).

$$\begin{aligned}
 \text{PHI_MC}_{4 \text{ to } 6, 4 \text{ to } 6} = \frac{\partial \dot{\mathbf{R}}}{\partial \dot{\mathbf{R}}_0} &= - \left[\frac{\dot{r} \mathbf{S}_1 + (\dot{g} - 1)/r}{r} \right] \mathbf{R} \mathbf{R}_0^T & \text{F3} \\
 &- \left[\frac{(\dot{g} - 1) \mathbf{S}_1}{r} \right] \mathbf{R} \dot{\mathbf{R}}_0^T + \dot{r} \mathbf{S}_2 \dot{\mathbf{R}} \mathbf{R}_0^T \\
 &+ (\dot{g} - 1) \mathbf{S}_2 \dot{\mathbf{R}} \dot{\mathbf{R}}_0^T + \dot{g} \mathbf{I} - \mathbf{U} \dot{\mathbf{R}} \dot{\mathbf{R}}_0^T
 \end{aligned}$$

Certain recurring groups of symbols may be collected to facilitate ease of coding and minimization of error. Each 3-by-3 submatrix of the 6-by-6 matrix PHI_MC results from the summation of 3-by-3 matrices generated by the dyadic product of groups of vectors of length three.

B. Interface Requirements. The input and output data are shown in table 4.2.5.2.

C. Processing Requirements. This subfunction is called by the following subfunctions:

REND_BIAS_AND_COV_PROF (section 4.2.5)

REND_NAV_INTERP (section 4.2.8.1.1)

D. Constraints. None

E. Supplementary Information. A suggested implementation in the form of a detailed flowchart may be found in Appendix B under the name of MEAN_CONIC_PARTIAL_TRANSITION_MATRIX_6X6.

F3 This equation shall be protected against division by zero (Reference 3.6-3).

4.2.5.2.1 Conic solution (F_AND_G).-- The conic solution subfunction utilized by the state vector interpolation, position-velocity submatrix of state transition matrix, and precision integration subfunctions shall provide the capability to trace the progress of a point along its orbit assuming pure Keplerian motion, by means of the F and G series algorithm in terms of the eccentric anomaly.

The variables F and G and \dot{F} and \dot{G} shall be calculated as functions of the difference in eccentric anomaly between an initial time at which a position and a velocity vector are known and a final time at which they are required.

If the final position and velocity are known, the difference in eccentric anomaly can be easily calculated and the F, G, \dot{F} and \dot{G} expressions can be obtained with the use of certain auxiliary variables called here S0, S1, S2, and S3.

If the final position and velocity are not known but only the transfer time, it is necessary to solve a form of Kepler's equation to obtain the difference in eccentric anomaly.

A. Detailed Requirements.-- The conic solution (F_AND_G) subfunction will be initiated by the call statement of the following form:

CALL: F_AND_G

IN LIST: SMA, DELTAT, C1, R_IN, R_IN_INV, R_FIN_INV, V_IN, D_IN, D_FIN

OUT LIST: F, G, FDOT, GDOT, S0, S1, S2, S3, R_FIN, R_FIN_INV, THETA

where:

SMA = semi-major axis of the conic

DELTAT = transfer time

C1 = an auxiliary constant, equal to the square root of SMA divided by the square root of Earth's gravitational constant

R_IN = the initial position vector (M50)

R_IN_INV = the reciprocal of the magnitude of R_IN

R_FIN_INV = the reciprocal of the magnitude of R_FIN (if unknown, a zero shall be input)

V_IN = the initial velocity vector (M50)

D_IN = the dot product of the initial position and velocity vectors

D_FIN = the dot product of the final position and velocity vectors (if unknown, a zero shall be input)

The conic solution subfunction shall perform the following in the order indicated:

1. Check the value of **R_FIN_INV** to see if Kepler's equation is to be solved.

IF R_FIN_INV = 0

- a. If **R_FIN_INV** \neq 0., which indicates that the final position vector is already known, the difference in eccentric anomaly shall be obtained from the expression

$$\text{THETA} = (C1(D_FIN - D_IN) + \text{DELTAT}/C1)/\text{SMA} \quad \text{F3}$$

- b. If **R_FIN_INV** = 0., the final position vector is to be calculated. This requires solving a modified form of Kepler's equation, which shall be accomplished by an iterative process that consists of the following steps:

- (1) Two auxiliary quantities shall be obtained from the input data:

$$\text{ONEMRIN} = (\text{SMA} - 1./\text{R_IN_INV})/\text{SMA} \quad \text{F3}$$

$$\text{D_MN_AN} = \text{DELTAT}/(C1 \text{ SMA}) \quad \text{F3}$$

D_MN_AN is the difference in mean anomaly, which shall be taken as a first approximation to the difference in eccentric anomaly, **THETA**. An iteration counter shall also be started.

$$\text{THETA} = \text{D_MN_AN}$$

$$\text{I} = 1$$

- (2) Then **THETA** and **THETA_COR** shall be recalculated until the number of iterations attains a predetermined maximum.

DO UNTIL

$$\text{I} = \text{NUM_KEP_ITER}$$

F3 This equation shall be protected against division by zero (Reference 3.6-3).

by repeatedly evaluating the equations

$$S0 = \cos (\text{THETA}) \quad \text{F9}$$

$$S1 = \sin (\text{THETA}) \quad \text{F9}$$

$$S2 = 1. - S0$$

$$\text{ERR} = D_MN_AN - \text{THETA} - D_IN \ C1 \ S2 / \text{SMA} + \text{ONEMRIN} \ S1 \quad \text{F3}$$

$$\text{THETA_COR} = \text{ERR} / (1. + D_IN \ C1 \ S1 / \text{SMA} - \text{ONEMRIN} \ S0) \quad \text{F3}$$

$$\text{THETA} = \text{THETA} + \text{THETA_COR}$$

$$I = I + 1$$

2. When the difference in eccentric anomaly is determined, certain auxiliary variables shall be calculated.

$$S0 = \cos (\text{THETA}) \quad \text{F9}$$

$$S1 = \sin (\text{THETA}) \quad \text{F9}$$

$$S2 = 1. - S0$$

$$S3 = \text{THETA} - S1$$

3. The values of F and G shall then be determined.

$$F = 1. - \text{SMA} \ S2 \ R_IN_INV$$

$$G = \text{DELTAT} - C1 \ \text{SMA} \ S3$$

4. If the final position vector and the reciprocal of its magnitude were not known, they shall be calculated:

$$\text{IF } R_FIN_INV = 0., \text{ then set}$$

$$R_FIN = F \ R_IN + G \ V_IN$$

$$R_FIN_INV = 1. / | R_FIN | \quad \text{F3}$$

5. The functions \dot{F} and \dot{G} , required for the calculation of the final velocity vector, shall be evaluated:

F3 This equation shall be protected against division by zero (Reference 3.6-3).

F9 This equation shall be protected against return value of sine or cosine with magnitude greater than unity (Reference 3.6-9).

FDOT = - EARTH_MU C1 S1 R_IN_INV R_FIN_INV

GDOT = 1. - SMA S2 R_FIN_INV

Finally, the out list of the conic solution subfunction shall contain the following quantities (different users require different sets of these):

F, G, FDOT, GDOT, SO, S1, S2, S3, R_FIN, R_FIN_INV, THETA

- B. Interface Requirements.-- Input and output parameters for the conic solution (F_AND_G) are given in table 4.2.5.2.1.
- C. Processing Requirements.-- The following are the code names of those subfunctions which call the F_AND_G conic solution subfunction:

PINES_METHOD

MEAN_CONIC_PARTIAL_TRANSITION_MATRIX_6x6

ONORBIT_SV_INTERP

- D. Constraints.-- None
- E. Supplementary Information.-- A suggested implementation of this subfunction in the form of a detailed flow diagram may be found in Appendix B under the following:

4.2.6 Rendezvous Sensor Measurement Selection (REND_SENSOR_SELECT)

The rendezvous sensor measurement selection subfunction shall perform the following tasks when in the rendezvous navigation phase, when the magnitude of the IMU sensed accelerations are below a predetermined threshold, and when on a covariance propagation cycle.

- Supply certain positive feedback flags to the REL_NAV display
- Select the proper rendezvous sensor navigation measurement incorporation subfunctions (section 4.2.8) to process the sensor angle data
- Select the type of data processing by the rendezvous navigation Kalman filter, REND_NAV_FILTER (sec. 4.2.8.1.2). Data are used to compute statistical parameters for display only, or data are used to update the state and covariance matrix as well as for the statistical computations
- Select the proper type of edit criteria to be used by the rendezvous navigation filter, REND_NAV_FILTER (section 4.2.8.1.2), in the bilevel edit test which determines if data are to be edited
- Reset the AUTO/INHIBIT/FORCE (AIF) flags so that a FORCE will be in effect for only one navigation filter cycle without being reset by the crew

A. Detailed Requirements.

1. The rendezvous sensor measurement selection subfunction initially sets certain positive feedback display parameters and then sets other appropriate flags to OFF so that the selection tasks are correctly accomplished. The following flags are required to be initialized upon each execution of the rendezvous sensor measurement selection subfunction.

- a. Certain positive feedback flags are defined for the REL_NAV display.

RDOT_AIF_DISPLAY = NAV_RDOT_AIF

RANGE_AIF_DISPLAY = NAV_RANGE_AIF

ANGLES_AIF_DISPLAY = NAV_ANGLES_AIF

DOING_MEAS_ENABLE = NAV_MEAS_ENABLE

- b. In order for this subfunction to properly select the appropriate rendezvous sensor navigation measurement incorporation subfunction for the proper angle set, the following flags (DO NAV flags) are initially set to OFF.

DO_RR_ANGLES_NAV = OFF

DO_ST_ANGLES_NAV = OFF

DO_COAS_ANGLES_NAV = OFF

- c. In order to properly process and record the type of processing of the data, the following flags are initially set to OFF.

(1) Statistical processing flags

RDOT_STAT = OFF
 ST_ANGLES_STAT = OFF
 COAS_ANGLES_STAT = OFF
 RANGE_STAT = OFF
 RR_ANGLES_STAT = OFF

(2) EDIT OVERRIDE flags for the bilevel edit test

RANGE_EDIT_OVERRIDE = OFF
 RDOT_EDIT_OVERRIDE = OFF
 RR_ANGLES_EDIT_OVERRIDE = OFF
 ST_ANGLES_EDIT_OVERRIDE = OFF
 COAS_ANGLES_EDIT_OVERRIDE = OFF

(3) A 4-dimensional array to record the type of processing of the data by the rendezvous sensor navigation measurement incorporation subfunction

SENSOR_EDIT = OFF

2. Next, a local flag (MEAS_STAT) is set to control measurement processing for statistical display purposes when in Major Mode 202.
 - a. MEAS_STAT = ON when NAV_MEAS_ENABLE = OFF and NAV_MM_202 = ON. This will result in measurement processing proceeding as if all the measurement AIF flags are set to INHIBIT, i.e., measurements are only used to compute statistical parameters for display purposes.
 - b. MEAS_STAT = OFF when NAV_MEAS_ENABLE = ON or NAV_MM_202 = OFF. This will result in the measurement data being processed in the nominal manner.
3. The NAV_RANGE_AIF switch and the MEAS_STAT flag are tested to appropriately set the RANGE_STAT flag and the RANGE_EDIT_OVERRIDE flag.
 - a. If either NAV_RANGE_AIF = INHIBIT or MEAS_STAT = ON then

RANGE_STAT = ON

resulting in the range measurement being processed for statistical display only.
 - b. If NAV_RANGE_AIF is not set to INHIBIT and MEAS_STAT = OFF then the NAV_RANGE_AIF flag is tested for a FORCE value.

- (1) If NAV_RANGE_AIF = FORCE then

RANGE_EDIT_OVERRIDE = ON

so that the edit criteria will be relaxed for the bilevel residual edit test.

4. Next, the NAV_RDOT_AIF switch and the MEAS_STAT flag are tested to appropriately set the RDOT_STAT flag and the RDOT_EDIT_OVERRIDE flag.

- a. If either NAV_RDOT_AIF = INHIBIT or MEAS_STAT = ON then

RDOT_STAT = ON,

resulting in the range rate measurement being processed for statistical display only.

- b. If NAV_RDOT_AIF is not set to INHIBIT and MEAS_STAT = OFF then the NAV_RDOT_AIF flag is tested for a FORCE value.

- (1) If NAV_RDOT_AIF = FORCE then

RDOT_EDIT_OVERRIDE = ON

so that the edit criteria will be relaxed for the bilevel residual edit test.

5. The NAV_RR_ANGLES_ENABLE switch is tested to see if the rendezvous radar angle set has been selected by the crew.

- a. If NAV_RR_ANGLES_ENABLE = ON then set

DO_RR_ANGLES_NAV = ON

so that the proper initialization procedure will take place for the angle data, and the rendezvous radar angles measurement incorporation subfunction will be executed.

- (1) Next, the NAV_ANGLES_AIF switch and the MEAS_STAT flags are tested to set the RR_ANGLES_STAT flag and the RR_ANGLES_EDIT_OVERRIDE flag.

- If either NAV_ANGLES_AIF = INHIBIT or MEAS_STAT = ON then

RR_ANGLES_STAT = ON,

resulting in the rendezvous radar angle measurements being processed for statistical display only.

- If NAV_ANGLES_AIF is not set to INHIBIT and MEAS_STAT = OFF the NAV_ANGLES_AIF flag is tested for a FORCE value.

If NAV_ANGLES_AIF = FORCE then

RR_ANGLES_EDIT_OVERRIDE = ON

so that the edit criteria will be relaxed for the bilevel residual edit test.

- b. If NAV_RR_ANGLES_ENABLE is not ON then the NAV_ST_ENABLE switch is tested to see if the star tracker angles set has been selected by the crew.

- (1) If NAV_ST_ENABLE = ON then set

DO_ST_ANGLES_NAV = ON

so that the proper initialization procedure will take place for the angle data and the star tracker measurement incorporation subfunction will be executed.

- Next, the NAV_ANGLES_AIF switch and the MEAS_STAT flags are tested to set the ST_ANGLES_STAT flag and the ST_ANGLES_EDIT_OVERRIDE flag.

If either NAV_ANGLES_AIF = INHIBIT or MEAS_STAT = ON then

ST_ANGLES_STAT = ON,

resulting in the star tracker angle measurements being processed for statistical display only.

If NAV_ANGLES_AIF is not set to INHIBIT and MEAS_STAT = OFF the NAV_ANGLES_AIF flag is tested for a FORCE value.

If NAV_ANGLES_AIF = FORCE then

ST_ANGLES_EDIT_OVERRIDE = ON

so that the edit criteria will be relaxed for the bilevel residual edit test.

- c. If NAV_RR_ANGLES_ENABLE = OFF and NAV_ST_ENABLE = OFF then the COAS angle data set is assumed to be enabled, thus

DO_COAS_ANGLES_NAV = ON

so that the proper initialization procedure will take place for the angle data and the COAS measurement incorporation subfunction will be executed.

- (1) Next, the NAV_ANGLES_AIF switch and the MEAS_STAT flags are tested to set the COAS_ANGLES_STAT flag and the COAS_ANGLES_EDIT_OVERRIDE flag.

- If either NAV_ANGLES_AIF = INHIBIT or MEAS_STAT = ON then

COAS_ANGLES_STAT = ON,

resulting in the COAS angle measurements being processed for statistical display only.

- If NAV_ANGLES_AIF is not set to INHIBIT and MEAS_STAT = OFF the NAV_ANGLES_AIF flag is tested for a FORCE value.

If NAV_ANGLES_AIF = FORCE then

COAS_ANGLES_EDIT_OVERRIDE = ON

so that the edit criteria will be relaxed for the bilevel residual edit test.

6. The NAV_RANGE_AIF flag is tested so that a FORCE value will be acknowledged for one navigation cycle without being reset by the crew.

a. If NAV_RANGE_AIF = FORCE then

RANGE_AIF = RANGE_AIF_LAST.

where the RANGE_AIF_LAST flag is a local flag which records the last non force value of the RANGE_AIF flag.

b. If NAV_RANGE_AIF is not equal to FORCE then

RANGE_AIF_LAST = RANGE_AIF.

7. Next, the NAV_RDOT_AIF flag is tested for the same reasons as given in 6.

a. If NAV_RDOT_AIF is equal to FORCE then

RDOT_AIF = RDOT_AIF_LAST.

b. If NAV_RDOT_AIF is not equal to FORCE then

RDOT_AIF_LAST = RDOT_AIF.

8. Finally, the NAV_ANGLES_AIF flag is tested similarly to 6 and 7.

a. If NAV_ANGLES_AIF = FORCE then

ANGLES_AIF = ANGLES_AIF_LAST.

b. If NAV_ANGLES_AIF is not equal to FORCE then

ANGLES_AIF_LAST = ANGLES_AIF.

- B. Interface Requirements. The input and output parameters for this subfunction are indicated in table 4.2.6.
- C. Processing Requirements. The sensor measurement selection subfunction shall be performed only when on a covariance propagation cycle and when the INU sensed accelerations are below a design dependent threshold (MEAS_THRESHOLD), i.e., NAV_MEAS = ON. This subfunction is called by the onorbit/rendezvous trunk logic, ONORBIT_RENDEZVOUS_NAV, and shall be executed before the sensor measurement initialization subfunction, REND_NAV_SENSOR_INIT.
- D. Constraints. The RANGE_AIF_LAST, RDOT_AIF_LAST and ANGLES_AIF_LAST flags need to be initialized to INHIBIT.
- E. Supplementary Information. A suggested implementation of this subfunction may be found in the Appendix B flowchart

4.2.7 Sensor Measurement Initialization (REND_NAV_SENSOR_INIT)

This sensor measurement initialization subfunction shall be invoked on each covariance propagation subcycle when the IMU sensed accelerations fall below a design dependent threshold (MEAS_THRESHOLD). The reinitialization of the sensor bias portion of the state vector and covariance matrix shall be performed upon entering rendezvous navigation, whenever the measurement type configuration has changed to include new measurements, or when an automatic in-flight update or a REL_NAV display update occurs while the Onorbit/Rendezvous Navigation principal function is active. The sensor covariance and bias setup subfunction (section 4.2.7.1) shall be invoked to account for the change in the measurement status.

A. Detailed Requirements. The following steps shall be performed (in the order indicated):

1. If the rendezvous radar range and range rate data set was off (DO_RRDOT_NAV_LAST = OFF) on the previous covariance propagation subcycle:

Call the sensor covariance and bias setup subfunction to reconfigure the bias portions of the state vector and the covariance matrix for this data set (see section 4.2.7.1)

CALL: SETUP

IN LIST: 2, TAU_RRDOT, BIAS_VAR_RRDOT, VAR_RRDOT,
RRDOT_BIAS_INIT

2. Test to determine if a new angle sensor has been selected by the crew.

- a. If the rendezvous radar angle data set has been made available since the previous covariance propagation subcycle (DO_RR_ANGLES_NAV = ON and DO_RR_ANGLES_NAV_LAST = OFF):

Call the sensor covariance and bias setup subfunction to reconfigure the bias portions of the state vector and the covariance matrix for this data set (see section 4.2.7.1).

CALL: SETUP

IN LIST: 0, TAU_RR_ANGLES, BIAS_VAR_RR_ANGLES, VAR_RR_ANGLES,
RR_ANGLES_BIAS_INIT

Also set the positive feedback flag to the display for rendezvous radar angles:

ANGLES_ENABLE_DISPLAY = 2

- b. If the star tracker angle data set has been made available since the previous covariance propagation subcycle (DO_ST_ANGLES_NAV = ON and DO_ST_ANGLES_NAV_LAST = OFF):

Call the sensor covariance and bias setup subfunction to reconfigure the bias portions of the state vector and the covariance matrix for this data set (see section 4.2.7.1).

CALL: SETUP

IN LIST: 0, TAU_ST_ANGLES, BIAS_VAR_ST_ANGLES,
VAR_ST_ANGLES, ST_ANGLES_BIAS_INIT

Also set the positive feedback flag to the display for star tracker angles:

ANGLES_ENABLE_DISPLAY = 0

- c. If the COAS angle data set has been made available since the previous covariance propagation subcycle (DO_COAS_ANGLES_NAV = ON and DO_COAS_ANGLES_NAV_LAST = OFF):

Call the sensor covariance and bias setup subfunction to reconfigure the bias portions of the state vector and the covariance matrix for this data set (see section 4.2.7.1).

CALL: SETUP

IN LIST: 0, TAU_COAS_ANGLES, BIAS_VAR_COAS_ANGLES,
VAR_COAS_ANGLES, COAS_ANGLES_BIAS_INIT

Also set the positive feedback flag to the display for COAS angles:

ANGLES_ENABLE_DISPLAY = 1

3. Save the current values of the "DO_NAV" flags for the next execution of this subfunction.

DO_RRDOT_NAV_LAST = ON

DO_RR_ANGLES_NAV_LAST = DO_RR_ANGLES_NAV

DO_ST_ANGLES_NAV_LAST = DO_ST_ANGLES_NAV

DO_COAS_ANGLES_NAV_LAST = DO_COAS_ANGLES_NAV

- B. Interface Requirements. The input and output variables for this subfunction are described in table 4.2.7.

- C. Processing Requirements. This subfunction is called by

NAV_ONORBIT_RENDEZVOUS (section 4.2.1)

- D. Constraints. None

- E. Supplementary Information. A suggested implementation in the form of a detailed flowchart can be found in Appendix B under the name:

4.2.7.1 Sensor Covariance and Bias Setup (SETUP)

The sensor measurement initialization subfunction (section 4.2.7) shall invoke the sensor covariance and bias setup subfunction to reconfigure the bias portions of the state vector and the covariance matrix whenever the covariance matrix initialization subfunction (REND_COV_INIT) has been exercised since the last covariance propagation subcycle, or when a new measurement set has been selected since the previous covariance propagation subcycle. New exponentially correlated time constants and process noise variances are also selected from premission values for use in the computation of the state transition matrix and in the addition of process noise.

- A. Detailed Requirements. This subfunction is called with the following internal variables in the IN LIST:

INLIST: I, TAU, BIAS_VAR, BIAS_COV_VAR, BIAS_INIT

where

I is a pointer for the desired measurement set

= 0 for all angle data

= 2 for rendezvous range and range rate data

TAU sensor time constants

BIAS_VAR sensor bias variances

BIAS_COV_VAR sensor bias variance terms for the covariance matrix

BIAS_INIT initial sensor bias

The following steps shall be performed for $J = 1$ to 2:

1. $K = I + J$
2. The state vector is to be reconfigured by setting its bias slots associated with the new measurement types to premission values. Bias values of measurement types no longer needed do not have to be zeroed.

$TAU_SENS_K = TAU_J$

$SENSOR_BIAS_K = BIAS_INIT_J$

$VAR_SENS_K = BIAS_VAR_J$

3. The covariance matrix is to be reconfigured by zeroing the off-diagonal terms associated with the new measurement type. The diagonal terms are then set equal to premission variance values of the new measurement type. The rows and columns associated with the discontinued measurement types do not have to be zeroed unless they are used by a new measurement type.

$$E_{9+K, 1 \text{ to } 13} = 0.0$$

$$E_{1 \text{ to } 13, 9+K} = 0.0$$

$$E_{9+K, 9+K} = \text{BIAS_COV_VAR}_j$$

4. The accept/reject counters and the edit ratio of the residual edit test for each measurement group must be reset to zero for use by the measurement processing statistics subfunction (section 4.2.9).

$$N_ACCEPT_K = 0$$

$$N_REJECT_K = 0$$

$$SEQ_ACCEPT_K = 0$$

$$SEQ_REJECT_K = 0$$

$$NAV_SIG_K = 0.0$$

- B. Interface Requirements. The input and output variables for this subfunction are defined in table 4.2.7.1.

- C. Processing Requirements. This subfunction is called by

REND_NAV_SENSOR_INIT (section 4.2.7)

- D. Constraints. None

- E. Supplementary Information. A suggested implementation in the form of a detailed flowchart can be found in Appendix B under the following name:

4.2.8 State and Covariance Measurement Incorporation

This section documents the requirements for the following four rendezvous sensor navigation measurement incorporation subfunctions:

- Rendezvous radar range and range rate measurements
- Rendezvous radar shaft and trunnion angle measurements
- Star tracker horizontal and vertical angle measurements
- COAS horizontal and vertical angle measurements

Each measurement incorporation subfunction updates the state vector and covariance matrix with the corresponding rendezvous sensor data using a 13-state process noise Kalman filter.

4.2.8.1 Rendezvous Radar Range and Range Rate Measurements (RRDOT_NAV)

This subfunction is responsible for the proper processing of the rendezvous radar range and range rate measurements. This subfunction shall perform the following tasks only when the rendezvous radar is not in the self test mode and the measurement data is labeled valid.

- Calculate the partial derivative of the measurement with respect to the estimated state at measurement time
- Compute the estimated measurement and the measurement residual
- Select the proper variances to model the uncorrelated measurement errors
- Store the old residual ratio, the EDIT OVERRIDE flag, and the STAT flags into temporary locations used by the Kalman Filter Updates subfunction (section 4.2.8.1.2)
- Schedule the Kalman Filter Updates subfunction to process the data
- Store the current residual ratio, the EDIT flag, and the measurement residual for display purposes

A. Detailed Requirements. The following steps shall be performed (in the order indicated):

1. If the rendezvous radar is not in the self test mode (SELF_TEST_FLAG = OFF), then continue with the measurement processing; otherwise exit this subfunction.
 - a. The time interval between the current filter time and the time of the radar measurement shall be computed:

$$\text{DELTAT_GO} = \text{T_CURRENT_FILT} - \text{T_REND_RADAR}$$

- b. Test the range data good flag. If the data is good, perform the following steps:

- (1) Call the measurement interpolation subfunction to interpolate the Orbiter state vector and the target state vector to the time of the range measurement (see section 4.2.8.1.1):

CALL: REND_NAV_INTERP

REND_NAV_INTERP subfunction shall also compute an Orbiter or target patch transition-matrix PHI_PATCH, the normalized line of sight vector I_RHO, and the magnitude of the relative position vector R_RHO used in this subfunction.

- (2) The rendezvous radar range measurement partial vector is computed with the following equations:

$$B_{1 \text{ to } 6} = -(\text{PHI_PATCH}_{1 \text{ to } 3, 1 \text{ to } 6})^T \underline{I_RHO}$$

$$B_{12} = 1.0$$

- (3) The estimated range measurement and the range measurement residual are then calculated:

$$\text{RNG} = \text{R_RHO_MAG} + \text{SENSOR_BIAS}_3$$

$$\text{DELQ} = \text{Q_RR_RNG} - \text{RNG}$$

- (4) The variance of the uncorrelated range measurement noise is computed:

$$\text{VAR} = (\text{SIG_RR_RNG} + \text{SLOPE_SIG_RR_RNG} \text{ R_RHO_MAG})^2$$

$$\text{VAR} = \text{MAXIMUM VAR, VAR_RR_RNG_MIN}$$

- (5) The residual test ratio from the previous filter cycle and the measurement processing control flags shall be set as follows:

where RANGE_EDIT_OVERRIDE and RANGE_STAT come from the sensor measurement selection subfunction (section 4.2.6) and the NAV_SIG₃ comes from the previous navigation cycle's execution of this subfunction as given in the forthcoming step (7).

- (6) The Kalman filter update subfunction (section 4.2.8.1.2) shall then be called to update the state and the covariance matrix:

CALL: REND_NAV_FILTER

- (7) The measurement edit flag, the residual test ratio, and the range measurement residual shall then be stored for subsequent computation of measurement processing statistics, as described in section 4.2.9:

SENSOR_EDIT₃ = EDIT_FLAG

NAV_SIG₃ = RESID_TEST_RATIO

SENSOR_DELQ₃ = DELQ

- c. Test the range rate data good flag. If the data is good, perform the following steps:

- (1) Call the measurement interpolation subfunction (section 4.2.8.1.1) to interpolate the Orbiter state vector and the target state vector to the time of the range rate measurement:

CALL: REND_NAV_INTERP.

REND_NAV_INTERP subfunction shall also compute an Orbiter or target patch transition matrix PHI_PATCH, the normalized line of sight vector $\underline{I_RHO}$, and the magnitude of the relative position vector R_RHO used in this subfunction.

- (2) The rendezvous radar range rate measurement partial vector is computed with the following equations:

$$\underline{U_RDOT} = \underline{V_RHO} / R_RHO_MAG \quad F3$$

$$B_{1 \text{ to } 3} = \underline{I_RHO} \times (\underline{I_RHO} \times \underline{U_RDOT})$$

$$B_{4 \text{ to } 6} = - \underline{I_RHO}$$

$$B_{1 \text{ to } 6} = (\text{PHI_PATCH})^T B_{1 \text{ to } 6}$$

$$B_{13} = 1.0$$

- (3) The estimated range rate measurement and the measurement residual are then calculated:

$$\text{RNG_DOT} = \underline{R_RHO} \cdot \underline{U_RDOT} + \text{SENSOR_BIAS}_4$$

$$\text{DELQ} = Q_RR_RNG_DOT - \text{RNG_DOT}$$

where $\underline{R_RHO}$ comes from the interpolation process.

F3 This equation shall be protected against division by zero (Reference 3.6-3).

- (4) The variance of the uncorrelated range rate measurement error is defined:

$$\text{VAR} = \text{VAR_RANGE_DOT}$$

- (5) The residual test ratio from the previous filter cycle and the filter processing control flags shall be set as follows:

$$\text{RESID_RATIO_OLD} = \text{NAV_SIG}_h$$

$$\text{MANUAL_EDIT_OVERRIDE} = \text{RDOT_EDIT_OVERRIDE}$$

$$\text{STAT_FLAG} = \text{RDOT_STAT}$$

where RDOT_EDIT_OVERRIDE and RDOT_STAT come from the sensor measurement selection subfunction (section 4.2.6) and the NAV_SIG_h comes from the previous navigation cycle's execution of this subfunction as given in the forthcoming step (7).

- (6) The Kalman filter subfunction (section 4.2.8.1.2) shall then be called to update the state and the covariance matrix:

$$\text{CALL: REND_NAV_FILTER}$$

- (7) The measurement edit flag, the residual test ratio, and the range rate measurement residual shall then be stored for subsequent computation of measurement processing statistics, as described in section 4.2.9:

$$\text{SENSOR_EDIT}_h = \text{EDIT_FLAG}$$

$$\text{NAV_SIG}_h = \text{RESID_TEST_RATIO}$$

$$\text{SENSOR_DELQ}_h = \text{DELQ}$$

B. Interface Requirements. The input and output variables for the rendezvous radar range and range rate measurement subfunction are given in table 4.2.8.1.

C. Processing Requirements. This subfunction is called by

$$\text{NAV_ONORBIT_RENDEZVOUS} \quad (\text{section 4.2.1})$$

D. Constraints. None

E. Supplementary Information. A suggested implementation in the form of a detailed flowchart can be found in Appendix B under the name:

4.2.8.1.1 Measurement interpolation (REND_NAV_INTERP).- The rendezvous navigation interpolation subfunction is invoked by the rendezvous sensor measurement incorporation subfunctions and is responsible for providing parameters that have been interpolated from current filter time back to the appropriate sensor measurement time. Specifically, this subfunction is charged with the following tasks.

- Invoke the onorbit state vector interpolation subfunction to interpolate both the Shuttle and target position and velocity vectors from current filter time to the time of the measurement
- Invoke the mean conic partial transition matrix subfunction to calculate a patch transition matrix from current filter time to the measurement time for either the Shuttle or target vehicle, depending on which vehicle state is to be updated by the Kalman filter
- Calculate the relative velocity, relative position vector, range, and the line of sight vector between the Shuttle and target. Each of these parameters is computed using the interpolated positions and velocities

A. Detailed Requirements. The following steps shall be performed (in the order indicated):

1. The Orbiter state vector shall be interpolated to the time of the measurement with the use of the state vector interpolation subfunction as described in section 4.2.8.1.1.1.

CALL: ONORBIT_SV_INTERP

IN LIST: R_LAST, V_LAST, R_FILT, V_FILT, DV_COV,
IGD, IGO, IDRAG, IVENT, ATFL_OV

OUT LIST: R_RESID, V_RESID, A_RESID

2. The target state vector shall be interpolated to the time of the measurement with the use of the state vector interpolation subfunction as described in section 4.2.8.1.1.1.

CALL: ONORBIT_SV_INTERP

IN LIST: R_TV_LAST, V_TV_LAST, R_TV, V_TV, 0.
GM_DEG, GM_ORD, DFL, VFL_TV, ATFL_TV

OUT LIST: R_TV_RESID, V_TV_RESID, A_TV_RESID

3. Next, the SHUTTLE_FILTER_FLAG is tested to see if the Shuttle state or the target state is to be included in the Kalman filter.

- a. If the Shuttle vehicle is the filter vehicle, then the position-velocity state transition submatrix subfunction is used to construct

an Orbiter patch transition matrix as described in section 4.2.5.2 for use in the measurement partial calculations.

CALL: MEAN_CONIC_PARTIAL_TRANSITION_MATRIX_6X6

IN LIST: $\underline{R_FILT}$, $\underline{V_FILT}$, $\underline{TOT_ACC}$, $\underline{R_RESID}$, $\underline{V_RESID}$,
 $\underline{A_RESID}$, $\underline{-DELTAT_GO}$

OUT LIST: $\underline{PHI_PATCH}$

- b. If the target vehicle is the filter vehicle, then the position-velocity state transition submatrix subfunction is used to construct a target patch transition matrix as described in section 4.2.5.2 for use in the measurement partials calculation.

CALL: MEAN_CONIC_PARTIAL_TRANSITION_MATRIX_6X6

IN LIST: $\underline{R_TV}$, $\underline{V_TV}$, $\underline{G_TV}$, $\underline{R_TV_RESID}$, $\underline{V_TV_RESID}$,
 $\underline{A_TV_RESID}$, $\underline{-DELTAT_GO}$

OUT LIST: $\underline{PHI_PATCH}$

4. The following auxiliary parameters will be calculated for use by the measurement subfunctions.

$$\underline{V_RHO} = \underline{V_TV_RESID} - \underline{V_RESID}$$

$$\underline{R_RHO} = \underline{R_TV_RESID} - \underline{R_RESID}$$

$$\underline{R_RHO_MAG} = \underline{R_RHO}$$

If $\underline{R_RHO_MAG}$ is less than a premission determined constant, $\underline{SENSOR_EPS}$, then

$$\underline{I_RHO_I} = \underline{SENSOR_DELTA} \text{ FOR } I = 1 \text{ to } 3$$

$$\underline{R_RHO_MAG} = \underline{SENSOR_DELTA}$$

Otherwise,

$$\underline{I_RHO} = \underline{R_RHO} / \underline{R_RHO_MAG}$$

F3

- B. Interface Requirements. The input and output data are shown in table 4.2.8.1.1.
- C. Processing Requirements. This subfunction is called by the following subfunctions:

F3 This equation shall be protected against division by zero (Reference 3.6-3).

** Initialization parameters, see section 4.7.

4.2.8.1.1.1. State vector interpolation (ONORBIT_SV_INTERP): The state vector interpolation subfunction shall provide the approximate position, velocity, and acceleration of either the Orbiter or target at a specified time within a given propagation interval given that the position, velocity and acceleration vectors are known at both ends of the interval.

The time at which vectors are desired is the time of an external sensor measurement, and the purpose of the interpolation is to enable the navigation filter to calculate measurement residuals at that time.

The method utilized for interpolation shall consist of defining a mean conic on the basis of positions and velocities of the vehicle in question at both ends of the propagation interval, and obtaining the desired vectors as if the vehicle moved along this mean conic. That is, a calculation shall be made to determine the point on the mean conic corresponding to the time of the measurement, and the velocity and position of such a point shall be taken as the state of the vehicle.

A. Detailed Requirements. This subfunction is called with the following internal variables in the IN LIST and the OUT LIST:

IN LIST: R_ONE, V_ONE, R_TWO, V_TWO, V_IMU_DIF, IGD, IGO,
IDM, IVM, IATM

OUT LIST: R_RESID, V_RESID, A_RESID

where

R_ONE } position and velocity of the vehicle at the previous
V_ONE } propagation step;

R_TWO }
V_TWO } current position and velocity

V_IMU_DIF difference between IMU accumulated sensed velocities at the current time and the previous time

IGD }
IGO } flags for the call to the acceleration function ACCEL_ONORBIT
IDM } (refer to section 4.2.3.1.4 for details of these flags)
IVM }
IATM }

The following steps shall be performed (in the order indicated):

1. A check of the absolute value of DELTAT_GO (where DELTAT_GO is the current filter time minus the time of the sensor measurement) against a premission-specified tolerance level will be performed:

$$|\text{DELTAT_GO}| \leq \text{EPS_TIME}$$

- a. If it is found that DELTAT_GO in absolute value is less than or equal to the tolerance, the values of the position and velocity of the vehicle at the current time shall be used as the state at the measurement time; the time tag at the measurement instant shall also be set equal to the current time:

$$\underline{R_RESID} = \underline{R_TWO}$$

$$\underline{V_RESID} = \underline{V_TWO}$$

$$\underline{T_RESID} = \underline{T_CURRENT_FILT}$$

- b. If, on the other hand, the difference between the time of the measurement and the current time exceeds the tolerance, perform the following:

- (1) Certain parameters associated with the mean conic shall be obtained

$$\underline{R_TWO_INV} = 1./|\underline{R_TWO}| \quad \text{F3}$$

$$\begin{aligned} \text{SMA} = 1./ & \left(1./|\underline{R_ONE}| + \underline{R_TWO_INV} \right. \\ & - (\underline{V_ONE} \cdot \underline{V_ONE} \\ & \left. + \underline{V_TWO} \cdot \underline{V_TWO}) / (2. \text{EARTH_MU}) \right) \quad \text{F3} \end{aligned}$$

$$\underline{C1} = \text{SQRT}(\text{SMA})/\text{SQRT_EMU} \quad \text{F3,F4}$$

$$\underline{D_TWO} = \underline{R_TWO} \cdot \underline{V_TWO}$$

and the time tag of the state vector at measurement time shall be set:

$$\underline{T_RESID} = \underline{T_CURRENT_FILT} - \underline{DELTAT_GO}$$

Additionally, set $\underline{R_FIN_TEMP_INV} = 0$.

- (2) The F and G series subfunction shall then be called (refer to section 4.2.5.2.1 for the description of this subfunction)

CALL: F_AND_G

F3 This equation shall be protected against division by zero (Reference 3.6-3).
 F4 This equation shall be protected against square roots of a negative number (Reference 3.6-4).

IN LIST: SMA, - DELTAT GO, C1, R TWO, R TWO INV,
R_FIN_TEMP_INV, V TWO, D TWO, D_FIN_TEMP

OUT LIST: F, G, FDOT, GDOT, S0, S1, S2, S3,
R_RESID, R_FIN_INV, THETA

The position vector (R_RESID) comes out of this call; the velocity vector (V_RESID) does not, but it can be calculated on the basis of FDOT and GDOT, which are also obtained from the F and G series call:

$$V_RESID = FDOT \ R_TWO + GDOT \ V_TWO$$

2. Finally, the modeled acceleration shall be obtained by invoking the acceleration function with the position, velocity, and time (determined by the above process) in the calling arguments and adding the central force term. The sensed acceleration shall be found by dividing the difference in accumulated sensed velocities at both ends of the propagation interval by the duration of the interval. Total acceleration will be the sum of these two.

$$A_RESID = ACCEL_ONORBIT (IGD, IGO, IDM, IVM, IATM, R_RESID, V_RESID, T_RESID) + V_IMU_DIF/DT_COV \ F3$$

(refer to section 4.2.4.1.1 for the description of this subfunction)

B. Interface Requirements. The input and output data are shown in table 4.2.8.1.1.1.

C. Processing Requirements. This subfunction is called by

REND_NAV_INTERP (section 4.2.8.1.1)

4.2.8.1.2 Kalman filter updates (REND_NAV_FILTER). - The Kalman Filter Updates subfunction shall be responsible for the processing of the rendezvous sensor measurement data. If the estimated range between the Orbiter and target vehicles is greater than or equal to a design dependent minimum range threshold, then the Kalman Filter Updates subfunction will perform the following major tasks.

- A bilevel residual edit test will be performed to determine whether the Kalman filter scheme will be used to update the state vector. This subfunction shall be able to respond to crew requests to relax the edit criteria thereby increasing the likelihood of incorporating the measurement data into the state vector.
- This subfunction shall be able to update the covariance matrix as well as the state vector by means of the Kalman update equations. The Kalman filter scheme shall be modified to allow for underweighting of the estimated sensor variance and the selective updating of the unmodeled acceleration bias states.
- Finally, the Kalman Filter Updates subfunction shall record the type of data processing that has occurred for crew display.

- A. Detailed Requirements. For the measurement type to be processed on this cycle, test the magnitude of the relative position vector (R_RHO_MAG) against the minimum separation distance (RNG_MIN) to determine whether or not to exercise the Kalman filter update equations.

If R_RHO_MAG < RNG_MIN, the EDIT_FLAG is to be set to OFF in order to blank the display. (Note: The measurement subfunction generates the partial vector, the residual, the magnitude of the relative position vector, and the a priori variance.) The logic then exits REND_NAV_FILTER without exercising the Kalman filter equations.

If R_RHO_MAG ≥ RNG_MIN, exercise the Kalman filter update equations, as follows:

1. Test the SHUTTLE_FILTER_FLAG. If the target is the filter vehicle (SHUTTLE_FILTER_FLAG = OFF), the sign is changed on the measurement partials vector.

$$B_1 \text{ to } 6 = -B_1 \text{ to } 6$$

2. The scalar quantity BT_E_B is to be calculated from the covariance matrix E and vector measurement partials B,

$$\underline{EB_COPY} = \underline{E} \underline{B}$$

$$\underline{BT_E_B} = \underline{B} \cdot \underline{EB_COPY},$$

where the second equation requires a dot product. The partials vector B shall then be set equal to zero so that subsequent measurement subroutines will only be required to calculate nonzero elements.

$$\underline{B} = 0.$$

The quantity MS_DELQ , which represents the expected variance in the residual, is then to be computed by

$$MS_DELQ = BT_E_B + VAR.$$

3. If the trace of the filter vehicle position portion of the covariance matrix ($E_{1,1} + E_{2,2} + E_{3,3}$) is greater than a threshold, $MS_POS_UND_WGT$, then the denominator of the Kalman gains is underweighted in order to improve the transient response of the filter.

$$MS_DELQ = MS_DELQ + K_UND_WGT(BT_E_B)$$

4. The residual test quantity ($RESID_TEST$) shall be computed for the residual edit test and for display purposes,

$$RESID_TEST = (K_RES_EDIT) MS_DELQ$$

where K_RES_EDIT is a premission constant.

5. The residual edit test ratio ($RESID_TEST_RATIO$) is to be computed.

$$RESID_TEST_RATIO = ABS(DELQ) / \sqrt{RESID_TEST}.$$

F3
F4

6. Test $STAT_FLAG$ to determine if the residual and residual ratio have been computed on this cycle for display purposes only. If $STAT_FLAG = ON$, set

$$EDIT_FLAG = STAT$$

for display (section 4.2.9) and exit $REND_NAV_FILTER$. If $STAT_FLAG$ is OFF, proceed to the next step in the logic.

7. Preparations for a residual edit test shall be performed. If the manual edit override is inactive, the test quantity ($TEST_VALUE$) shall be set

OLD is the value of the residual ratio for the test being processed as calculated by the state and covariance measurement incorporation subfunction during the previous navigation cycle.

F3 This equation shall be protected against division by zero (Reference 3.6-3).

F4 This equation shall be protected against square roots of a negative number (Reference 3.6-4).

8. The edit test ($\text{RESID_TEST_RATIO} \leq \text{TEST_VALUE}$) is performed.

- a. If the test fails, the edit flag is set to ON for crew information.

$\text{EDIT_FLAG} = \text{ON}$

- b. If the measurements are to be incorporated, then update the state and the covariance matrix.

EXECUTE: $\text{REND_STATE_AND_COV_UPDATE CODE}$

- (1) Compute the Kalman filter gain and update and symmetrize the covariance matrix.

$\underline{\text{OMEGA}} = \underline{\text{EB_COPY}} / \text{MS_DELQ}$ F3

$\text{E}_{I,I} = \text{E}_{I,I} - \text{OMEGA}_I \text{EB_COPY}_I$

$\text{E}_{I,J} = \text{E}_{I,J} - \text{OMEGA}_I \text{EB_COPY}_J$ for $I = 1, 12$ and
 $J = I + 1, 13$

$\text{E}_{J,I} = \text{E}_{I,J}$

Finally, $\text{E}_{13,13} = \text{E}_{13,13} - \text{OMEGA}_{13} \text{EB_COPY}_{13}$.

- (2) Test the $\text{SHUTTLE_FILTER_FLAG}$.

- If the Shuttle vehicle is the filter vehicle ($\text{SHUTTLE_FILTER_FLAG} = \text{ON}$), then this subfunction shall update the shuttle state vector by application of the following equations:

$\underline{\text{R_FILT}} = \underline{\text{R_FILT}} + \text{OMEGA}_{1 \text{ to } 3} \text{DELQ}$

$\underline{\text{V_FILT}} = \underline{\text{V_FILT}} + \text{OMEGA}_{4 \text{ to } 6} \text{DELQ}$

- If the target vehicle is the filter vehicle ($\text{SHUTTLE_FILTER_FLAG} = \text{OFF}$), then this subfunction shall update the target state vector by application of the following equations:

$\underline{\text{R_TV}} = \underline{\text{R_TV}} + \text{OMEGA}_{1 \text{ to } 3} \text{DELQ}$

$\underline{\text{V_TV}} = \underline{\text{V_TV}} + \text{OMEGA}_{4 \text{ to } 6} \text{DELQ}$

- (3) If the unmodeled acceleration bias states are to be updated ($\text{UNMOD_ACC_BIAS_UPDATE_FLAG} = \text{ON}$), then this subfunction shall update the unmodeled acceleration bias states by application of the following equation:

F3 The equation shall be protected against division by zero (Reference 3.6-3).

$$\text{UNMOD_ACC_BIAS} = \text{UNMOD_ACC_BIAS} + \text{OMEGA}_{7 \text{ to } 9} \text{ DELQ}$$

- (4) The sensor bias states shall be updated by application of the following equation:

$$\text{SENSOR_BIAS} = \text{SENSOR_BIAS} + \text{OMEGA}_{10 \text{ to } 13} \text{ DELQ}$$

where DELQ corresponds to the appropriate measurement residual.

After executing REND_STATE_AND_COV_UPDATE code, if the manual edit override is active (MANUAL_EDIT_OVERRIDE = ON), the edit flag is set to FORCED.

EDIT_FLAG = FORCED

Otherwise, set the edit flag to PROCESSED.

EDIT_FLAG = PROCESSED

Both the FORCED and the PROCESSED conditions result from measurement incorporation.

It is required that the residual, the residual test quantity (RESID_TEST_RATIO), and the residual edit flag corresponding to each measurement subfunction be saved for display purposes.

- B. Interface Requirements. The inputs and outputs for this subfunction are given in table 4.2.8.1.2.
- C. Processing Requirements. This subfunction is called by the following subfunctions:

ANGLE_NAV (section 4.2.8.3.1)

RR_ANGLE_NAV (section 4.2.8.2)

RRDOT_NAV (section 4.2.8.1)

- D. Constraints. None

- E. Supplementary Information. A suggested implementation in the form of detailed flowcharts can be found in Appendix B under the following names:

4.2.8.2 Rendezvous Radar Shaft and Trunnion Angle Measurements (RR_ANGLE_NAV)

This subfunction is responsible for the proper processing of the rendezvous radar shaft and trunnion angle measurements. This subfunction shall perform the following tasks only when the rendezvous radar is not in the self test mode and the measurement data is labeled valid.

- Calculate the partial derivative of the measurement with respect to the estimated state at measurement time.
 - Compute the estimated measurement and the measurement residual.
 - Select the proper variances to model the uncorrelated measurement errors.
 - Store the old residual ratio, the EDIT OVERRIDE flag, and the STAT flags into temporary locations used by the Kalman Filter Updates subfunction (section 4.2.8.1.2).
 - Schedule the Kalman Filter Updates subfunction to process the data.
 - Store the current residual ratio, the EDIT flag and the measurement residual for display purposes.
- A. Detailed Requirements.- Process the rendezvous radar angle data only if the data are valid and the rendezvous radar is not in the self test mode (SELF_TEST_FLAG = OFF). The following steps shall be performed in the order indicated.
1. Compute the mean of 1950 to sensor coordinate transformation matrix.

$$M_M50_TO_SENSOR = M_BODY_TO_RR \quad QUAT_TO_MAT(Q_M50BODY_RR)$$
 2. Compute the time difference between current filter time and the time of the rendezvous radar angle data measurements.

$$DELTAT_GO = T_CURRENT_FILT - T_REND_RADAR$$
 3. Call the measurement interpolation subfunction and interpolate the Orbiter and target state vectors to the time of the shaft angle measurement (see section 4.2.8.1.1)

$$CALL: \quad REND_NAV_INTERP$$
 4. Call the angle partials subfunction to compute the partial vector (see section 4.2.8.2.1)

$$CALL: \quad REND_ANGLE_PARTIALS$$

$$IN \ LIST: \quad -M_M50_TO_SENSOR_{3,1} \text{ to } 3$$
 5. Calculation of the partial vector is completed by setting the appropriate value in the bias slot of that vector.

$$B_{10} = 1.0$$

6. Compute the estimated shaft angle measurement and the shaft angle measurement residual.

$$\text{SHAFT} = \text{ARCTAN2} (-U_{M2}, U_{M1}) + \text{SENSOR_BIAS}_1 \quad \text{F7}$$

$$\text{DELQ} = Q_{RR_SHFT} \text{ RAD_PER_DEG} - \text{SHAFT}$$

7. If measurement residual (DELQ) falls outside the range $-\pi$ to π , adjust DELQ such that it falls inside the range.

$$\text{If } \text{DELQ} > 0. \quad \text{DELQ} = \text{DELQ} - 2\pi$$

$$\text{DELQ} \leq 0. \quad \text{DELQ} = \text{DELQ} + 2\pi$$

8. Assign the appropriate variance for the rendezvous radar shaft angle.

$$\text{VAR} = \text{VAR_SHAFT}$$

9. The residual test ratio from the previous filter cycle and the measurement processing control flags shall be set as follows:

$$\begin{aligned} \text{RESID_RATIO_OLD} &= \text{MAX} (\text{NAV_SIG}_1, \text{NAV_SIG}_2) \\ \text{MANUAL_EDIT_OVERRIDE} &= \text{RR_ANGLES_EDIT_OVERRIDE} \\ \text{STAT_FLAG} &= \text{RR_ANGLES_STAT} \end{aligned}$$

(where RR_ANGLES_EDIT_OVERRIDE and RR_ANGLES_STAT come from the sensor measurement selection subfunction (section 4.2.6) and NAV_SIG comes from the previous execution of this subfunction as given in step 11).

10. Call the Kalman filter subfunction to process the rendezvous radar shaft angle measurement (see section 4.2.8.1.2)

$$\text{CALL: } \text{REND_NAV_FILTER}$$

11. Store the output data from the Kalman filter subfunction in the appropriate variables for use by the measurement processing statistics subfunction.

$$\text{SENSOR_EDIT}_1 = \text{EDIT_FLAG}$$

$$\text{NAV_SIG}_1 = \text{RESID_TEST_RATIO}$$

$$\text{SENSOR_DELQ}_1 = \text{DELQ}$$

F7 This equation shall be protected against arc tangents with both arguments equal to zero (Reference 3.6-7).

12. Call the measurement interpolation subfunction to interpolate the Orbiter and target state vectors to the time of the trunnion angle measurement (see section 4.2.8.1.1)

CALL: REND_NAV_INTERP

13. Call the angle partials subfunction to compute the partial vector (see section 4.2.8.2.1)

CALL: REND_ANGLE_PARTIALS

IN LIST: UNIT(I_RHO x M_M50_TO_SENSOR_{3,1to3})

14. Calculation of the partial vector is completed by setting the appropriate value in the bias slot of that vector.

$$B_{11} = 1.0$$

15. Compute the estimated trunnion angle measurement and the trunnion angle measurement residual.

$$TRUN = \text{ARCSIN}(U_{M_3}) + \text{SENSOR_BIAS}_2$$

F5

$$\text{DELQ} = Q_{RR_TRUN} \text{ RAD_PER_DEG} - TRUN$$

16. Assign the appropriate variance for the rendezvous radar trunnion angle

$$\text{VAR} = \text{VAR_TRUN}$$

17. Call the Kalman filter to process the rendezvous radar trunnion angle measurement (see section 4.2.8.1.2)

CALL: REND_NAV_FILTER

- B. Interface Requirements. - The input and output variables for this subfunction are defined in table 4.2.8.2.

F5 This equation shall be protected against arc sine of arguments with magnitudes greater than unity (Reference 3.6-5).

- C. Processing Requirements.-- This subfunction is called by NAV_ONORBIT_RENDEZVOUS (section 4.2.1).
- D. Constraints.-- None
- E. Supplementary Information.-- A suggested implementation in the form of a detailed flowchart can be found in Appendix B under the name RR_ANGLE_NAV.

4.2.8.2.1 Angle partials (REND_ANGLE_PARTIALS)

The angle partials subfunction (REND_ANGLES_PARTIALS) is a utility subfunction whose purpose is to compute the angle measurement partial derivatives, with respect to the Orbiter position and velocity, for all sensor angle measurements. The partials vector is used by the Kalman filter update subfunction, REND_NAV_FILTER (section 4.2.8.1.2).

A. Detailed Requirements.-

1. First, we compute RHO_PLANE, which is the projection of the Shuttle/target relative position vector, R_RHO, into the orthogonal complement plane of the axis of rotation of the angle measurement,

$$\underline{RHO_PLANE} = \underline{R_RHO} - (\underline{R_RHO} \cdot \underline{I_N})\underline{I_N},$$

where I_N is a unit vector along the axis of rotation.

2. Next, the partial derivative of the angle measurement with respect to the Shuttle position and velocity is computed.

$$B_{1 \text{ to } 6} = (\text{PHI_PATCH}_{1 \text{ to } 3, 1 \text{ to } 6})^T.$$

F3

$$(\text{UNIT}(\underline{RHO_PLANE} \times \underline{I_N}) / |\underline{RHO_PLANE}|$$

PHI_PATCH is the position-velocity part of the state transition matrix calculated in the measurement interpolation subfunction, REND_NAV_INTERP (section 4.2.8.1.1).

3. Finally, the unit vector in the line of sight direction, I_RHO, is rotated into sensor coordinates

$$\underline{U_M} = \text{M_M50_TO_SENSOR } \underline{I_RHO}$$

- B. Interface Requirements.- Input and output parameters are listed in table 4.2.8.2.1.

- C. Processing Requirements.- This subfunction is called by the following subfunctions:

ANGLE_NAV (section 4.2.8.3.1)
RR_ANGLE_NAV (section 4.2.8.2)

- D. Constraints.- None

- E. Supplemental Information.- A suggested implementation of the angle partials subfunction may be found in the Appendix B flowchart REND_ANGLE_PARTIALS.

F3 This equation shall be protected against division by zero (Reference 3.6-3).

4.2.8.3 Star Tracker Horizontal and Vertical Measurements (STAR_TRACKER_NAV)

This subfunction is responsible for the proper processing of the star tracker vertical and horizontal measurement data. This subfunction shall perform the following tasks provided the star tracker is in the target track mode and the angle data are valid.

- Store the mean of '50 to star tracker transformation matrix for use in the angle measurements subfunction.
- Compute the time difference between current filter time and measurement time.
- Invoke the angle measurement subfunction for the processing of the angle data with the proper IN LIST arguments.

If the star tracker time tag is too close in value to the star tracker time tag on the last filter cycle the angle measurement subfunction is not invoked in order to avoid the processing of the same measurement twice.

A. Detailed Requirements.-- If the star tracker data is good (ST_DATA_GOOD = ON) and the star tracker is in the target track mode (TRG_TRK_MODE = ON), then the following steps shall be performed in the order indicated.

1. Store the mean of 1950 to star tracker transformation matrix into the mean of 1950 to sensor transformation matrix for use in the angle measurements subfunction (section 4.2.8.3.1)

M_M50_TO_SENSOR = M_M50_TO_ST

2. Compute both the time difference between the current time and the star tracker measurement time and the time difference between the current star tracker measurement time and the time of the last processed measurement.

DELTAT_GO = T_CURRENT_FILT-T_STAR_TRACKER
DELTAT_ST = T_STAR_TRACKER-T_ST_LAST

3. Test the time difference between the current star tracker measurement time and the time of the last processed measurement to avoid the redundant processing of the star tracker data.

If DELTAT_ST is larger than a premission time difference, then

- a. Invoke the angle measurement subfunction to incorporate the star tracker angle data into the filter vehicle state.

CALL: ANGLE_NAV

IN LIST: VAR ST_HORIZ, Q ST_HORIZ, VAR ST_VERT,
Q ST_VERT, ST_ANGLES_EDIT_OVERRIDE,
ST_ANGLES_STAT

b. Set the time of the last Star tracker measurement.

T_ST_LAST = T_STAR_TRACKER

- B. Interface Requirements. - The input and output variables for this subfunction are defined in table 4.2.8.3.
- C. Processing Requirements. - This subfunction is called by NAV_ONORBIT_RENDEZVOUS (section 4.2.1).
- D. Constraints. - None
- E. Supplementary Information. - A suggested implementation in the form of a detailed flowchart can be found in Appendix B under the name STAR_TRACKER_NAV.

4.2.8.3.1 Angle measurements (ANGLE_NAV)

This utility subfunction is responsible for the proper processing of vertical and horizontal angle measurements taken by either the COAS or star tracker. This subfunction shall perform the following tasks when called by either the COAS or star tracker vertical and horizontal measurements subfunction (see sections 4.2.8.4 and 4.2.8.3, respectively):

- Calculate the partial derivative of the measurement with respect to the estimated state at measurement time.
- Compute the estimated measurement and the measurement residual.
- Select the proper variances to model the uncorrelated measurement errors.
- Store the old residual ratio, the EDIT OVERRIDE flag, and the STAT flags into temporary locations used by the Kalman filter Updates subfunction (section 4.2.8.1.2).
- Schedule the Kalman filter Updates subfunction to process the data.
- Store the current residual ratio, the EDIT flag, and the measurement residual for display purposes.

A. Detailed Requirements.-- This subfunction is called with the following internal variables in the IN LIST:

IN LIST: VAR_HORIZ, Q_HORIZ, VAR_VERT, Q_VERT,
ANGLES_MANUAL_EDIT_OVERRIDE, ANGLES_STAT_FLAG

where

VAR_HORIZ variance of the horizontal measurement

Q_HORIZ horizontal angle measurement

VAR_VERT variance of the vertical measurement

Q_VERT vertical angle measurement

ANGLES_MANUAL_EDIT_OVERRIDE manual edit override flag

ANGLES_STAT_FLAG stat flag

The following steps shall be performed (in the order indicated):

1. Call the measurement interpolation subfunction to interpolate the Orbiter and target state vectors to the time of the vertical angle measurement (see section 4.2.8.1.1).

CALL: REND_NAV_INTERP

2. Call the angle partials subfunction to compute the partial vector (see section 4.2.8.2.1)

CALL: REND_ANGLE_PARTIALS

IN LIST: -M_M50_TO_SENSOR_{2,1} to 3

3. Calculation of the partial vector is completed by setting the appropriate value in the bias slot of that vector:

B₁₁ = 1.0

4. Compute the estimated vertical angle measurement and the vertical angle measurement residual.

VERT = ARCTAN2(-U_{M1}, U_{M3}) + SENSOR_BIAS₂ F7

DELQ = C_VERT - VERT

5. Assign the appropriate variance for the vertical angle

VAR = VAR_VERT

6. Set up the required inputs to the Kalman filter subfunction:

RESID_RATIO_OLD = MAX (NAV_SIG₁, NAV_SIG₂)

MANUAL_EDIT_OVERRIDE = ANGLES_MANUAL_EDIT_OVERRIDE

STAT_FLAG = ANGLES_STAT_FLAG

7. Call the Kalman filter subfunction to process the vertical angle measurement (see section 4.2.8.1.2).

CALL: REND_NAV_FILTER

8. Store the output data from the Kalman filter subfunction in the appropriate variables for use by the measurement processing statistics subfunction.

SENSOR_DELQ₂ = DELQ

NAV_SIG₂ = RESID_TEST_RATIO

SENSOR_EDIT₂ = EDIT_FLAG

F7 This equation shall be protected against arc tangents with both arguments equal to zero (Reference 3.6-7).

9. Call the measurement interpolation subfunction to interpolate the Orbiter and target state vectors to the time of the horizontal angle measurement (see section 4.2.8.1.1).

CALL: REND_NAV_INTERP

10. Call the angle partials subfunction to compute the partial vector (see section 4.2.8.2.1).

CALL: REND_ANGLE_PARTIALS

IN LIST: -M_M50_TO_SENSOR₁, 1 to 3

11. Calculation of the partial vector is completed by setting the appropriate value in the bias slot of that vector:

$$B_{10} = 1.0$$

12. Compute the estimated horizontal angle measurement and the horizontal angle measurement residual.

$$\text{HORIZ} = \text{ARCTAN2} (U_{M2}, U_{M3}) + \text{SENSOR_BIAS}_1$$

F7

$$\text{DELQ} = Q_{\text{HORIZ}} - \text{HORIZ}$$

13. Assign the appropriate variance for the horizontal angle

$$\text{VAR} = \text{VAR_HORIZ}$$

14. Call the Kalman filter subfunction to process the horizontal angle measurement (see section 4.2.8.1.2).

CALL: REND_NAV_FILTER

15. Store the output data from the Kalman filter subfunction in the appropriate variables for use by the measurement processing statistics subfunction.

$$\text{SENSOR_DELQ}_1 = \text{DELQ}$$

$$\text{NAV_SIG}_1 = \text{RESID_TEST_RATIO}$$

$$\text{SENSOR_EDIT}_1 = \text{EDIT_FLAG}$$

- B. Interface Requirements. - The input and output variables for this subfunction are defined in table 4.2.8.3.1.

F7 This equation shall be protected against arc tangents with both arguments equal to zero (Reference 3.6-7).

- C. Processing Requirements. - This subfunction is called by the following subfunctions:

COAS_NAV (section 4.2.8.4)
STAR_TRACKER_NAV (section 4.2.8.3)

- D. Constraints. - None

- E. Supplementary Information. - A suggested implementation of this subfunction in the form of a detailed flowchart can be found in Appendix B under the name

ANGLE_NAV.

4.2.8.4 COAS Horizontal And Vertical Angle Measurements (COAS_NAV)

This subfunction is responsible for the proper processing of the COAS horizontal and vertical angle measurements. This subfunction shall perform the following task if the COAS data are labeled valid.

- Compute the time difference between current filter time and measurement time. Also we will compute the time difference (DELTAT_COAS) between the current COAS measurement and the measurement last used by this subfunction.
- If DELTAT_COAS satisfies criteria for staleness and is not greater than a design dependent threshold, the angle measurement subfunction shall be invoked to process the vertical and horizontal angle data.
- If the COAS horizontal and vertical angle measurement subfunction is not to process the angle data for statistical display purposes only, then the time of the last COAS measurement is reset.

A. Detailed Requirements. - If the COAS data is good (COAS_DATA_GOOD = ON), then the following steps shall be performed (in the order indicated):

1. Determine the delta time between the current time and the time of the COAS measurements and also determine the delta time since the last processing of COAS data.

DELTAT_GO = T_CURRENT_FILT - T_COAS
DELTAT_COAS = T_COAS - T_COAS_LAST

2. This subfunction will only process COAS data if the COAS data have not been previously processed and the time elapsed since the COAS data snap is smaller than a design dependent time delta.

i.e., if DELTAT_COAS > DELTAT_COAS_MIN

AND

DELTAT_GO < DELTAT_COAS_MAX

- a. Compute the mean of 1950 to sensor coordinate transformation matrix.

M_M50_TO_SENSOR = M_BODY_TO_COAS COAS_ID M_M50_TO_BODY_COAS

- b. Call the angle measurements subfunction to incorporate the COAS angle data (see section 4.2.8.3.1).

CALL: ANGLE_NAV

IN LIST: VAR_COAS_HORIZ, Q_COAS_HORIZ,
VAR_COAS_VERT, Q_COAS_VERT,
COAS_ANGLES_EDIT_OVERRIDE,
COAS_ANGLES_STAT

- c. If the COAS data were processed (COAS ANGLES STAT = OFF), save the time of the COAS data for use on the next filter subcycle.

T_COAS_LAST = T_COAS

- B. Interface Requirements.-- The input and output variables for this subfunction are defined in table 4.2.8.4.
- C. Processing Requirements.-- This subfunction is called by NAV_ONORBIT_RENDEZVOUS (section 4.2.1).
- D. Constraints.-- None
- E. Supplementary Information.-- A suggested implementation in the form of a detailed flowchart can be found in Appendix B under the name COAS_NAV.

4.2.9 Measurement Processing Statistics (MEAS_PROCESSING_STATISTICS-REND)

During rendezvous navigation phases that utilize external measurements, the measurement processing statistics subfunction will compute for display certain parameters that are indicative of the condition of the navigation filter and the external sensor measurements that it utilizes. These display parameters serve as the basis for the crew decision as to how external measurement data are to be processed by the nav filter.

The measurement processing statistics subfunction will be performed after the state and covariance measurement incorporation subfunctions have been performed. Filter edit indicators, which will have been initialized to a default value during the sensor measurement selection subfunction, will be redefined during performance of the state and covariance measurement incorporation subfunctions. This will indicate to the measurement processing statistics subfunction, for each measurement type being utilized, which of the following five cases has occurred:

- Edit indicator = OFF - The filter was not configured for the measurement type or the data were bad and the filter did not attempt to process data of that type.
- Edit indicator = ON - The filter did attempt to process the measurement type but automatically edited the data.
- Edit indicator = PROCESSED - The filter processed the measurement type as a result of the data satisfying the edit criterion.
- Edit indicator = STAT - The filter was used solely for producing the residual and ratio parameters for display.
- Edit indicator = FORCED - The filter processed the data as a result of a crew edit override.

Moreover, the state and covariance measurement incorporation subfunction will provide the measurement processing statistics subfunction with the value of each measurement residual and the corresponding residual edit ratio value. The data supplied to the measurement processing statistics subfunction are used to compute statistics for the sensor measurement type selected.

For each measurement type, the following parameters are to be computed for display to show how well the navigation filter is processing external measurements of that particular type:

$DISP_DELQ_I$ - The actual measurement residual computed by the nav filter for the I th measurement type.

$DISP_SIG_I$ - The residual edit ratio for the I th measurement type. The ratio is the absolute value of the measurement residual divided by the square root of the scaled value of the residual variance for the measurement type. (See section 4.2.8.1.2 for the definition of $RESID_TEST_RATIO$.)

N_ACCEPT_I - The number of data marks for the I th measurement type which have been used to update the nav state vector.

N_REJECT_I - The number of data marks for the I th measurement type which have been automatically rejected as a result of failing the nav filter edit criterion.

$DISP_EDIT_I$ - The status indicator which shall be displayed as a BLANK unless the nav filter has edited a predetermined number of sequential data marks for the I th type. In this case, the status indicator shall be displayed as the symbol, \downarrow . Once set, the down arrow symbol shall continue to be displayed until a predetermined number of sequential data marks have been processed by the nav filter, or until a data mark has been processed by the nav filter as a result of the crew setting the appropriate AUTO/INHIBIT/FORCE flag to FORCE.

If valid data were not presented to the filter or if the estimated distance between vehicles is less than a specified value ($RANGE_MIN$), then these parameters will maintain the values defined during the previous filter subcycle.

The ACCEPT/REJECT counters are initialized to zero whenever the covariance matrix is reinitialized, when leaving rendezvous navigation, when the corresponding sensor type is changed, or when the IMU sensed accelerations exceed a premission specified amount ($MEAS_THRESHOLD$).

Sensor data will consist of two types: angular data and range data. The angular data will consist of a pair of angles from one of three mutually exclusive sources - COAS, star tracker (ST), or rendezvous radar (RR). The range data will consist of range and range rate from the rendezvous radar. Angular data, from whichever source has been chosen, can be utilized in conjunction with range data.

A. Detailed Requirements. - The correspondence between the measurement type and the subscript, I , shall be as follows:

$I = 1$ - COAS horizontal angle, ST horizontal angle, or RR shaft

For each value of the integer I in the interval $(1,4]$, the following steps shall be performed (in the order indicated) when $SENSOR_EDIT_I \neq OFF$:

1. $DISP_DELQ_I$ and $DISP_SIG_I$ are given the values:

$$\text{DISP_DELQ}_I = \text{SENSOR_DELQ}_I$$

$$\text{DISP_SIG}_I = \text{NAV_SIG}_I$$

where SENSOR_DELQ_I and NAV_SIG_I were computed in the state and covariance measurement incorporation subfunctions (sections 4.2.8.1 through 4.2.8.4).

2. For the range measurement,

$$I = 3,$$

the residual is converted to kilofeet:

$$\text{DISP_DELQ}_I = \text{DISP_DELQ}_I / 1000.0$$

3. For the angle measurements,

$$I = 1 \text{ or } 2,$$

the residuals are converted to degrees:

$$\text{DISP_DELQ}_I = \text{DISP_DELQ}_I \text{ DEG_PER_RAD}$$

4. Test the SENSOR_EDIT value for the I th measurement type

- a. If $\text{SENSOR_EDIT}_I = \text{STAT}$, DISP_EDIT_I shall be given the value BLANK:

$$\text{DISP_EDIT}_I = \text{BLANK}$$

The logic then exits from $\text{MEAS_PROCESSING_STATISTICS_REND}$.

- b. If $\text{SENSOR_EDIT}_I \neq \text{STAT}$, then test SENSOR_EDIT again.

- (1) If $\text{SENSOR_EDIT}_I = \text{ON}$, the sequential accept counter shall be set to zero:

$$\text{SEQ_ACCEPT}_I = 0,$$

the counter for the number of marks rejected by the nav filter shall be incremented by one:

$$\text{N_REJECT}_I = \text{N_REJECT}_I + 1,$$

and the sequential reject counter shall be incremented by one:

$$\text{SEQ_REJECT}_I = \text{SEQ_REJECT}_I + 1$$

If SEQ_REJECT_I is found to exceed a predetermined number, REJ_MAX , $DISP_EDIT_I$ shall be set to \downarrow to indicate that a number of sequential data marks have been edited.

$DISP_EDIT_I = \downarrow$

- (2) If $SENSOR_EDIT_I \neq ON$, then the sequential reject counter shall be set to zero:

$SEQ_REJECT_I = 0$,

the counter for the number of marks processed by the nav filter shall be incremented:

$N_ACCEPT_I = N_ACCEPT_I + 1$,

and the sequential accept counter shall be also incremented:

$SEQ_ACCEPT_I = SEQ_ACCEPT_I + 1$

If SEQ_ACCEPT_I exceeds a pre-determined number ACC_MIN , or $SENSOR_EDIT_I$ has a value of FORCED, $DISP_EDIT_I$ is given the value BLANK:

$DISP_EDIT_I = BLANK$

If the indicator $SENSOR_EDIT_I$ is found to have the value OFF on the initial check, both $DISP_DELQ_I$ and $DISP_SIG_I$ shall maintain the previous values from the prior filter subcycle.

- B. Interface Requirements.- Input and output parameters are listed in table 4.2.9.
- C. Processing Requirements.- This subfunction is called by NAV_ONORBIT_RENDEZVOUS (section 4.2.1).
- D. Constraints.- None
- E. Supplementary Information.- A suggested implementation for this subfunction may be found in the detailed flow chart of Appendix B entitled MEAS_PROCESSING_STATISTICS_REND.

4.3 ONORBIT PRECISION STATE PREDICTION PRINCIPAL FUNCTION

A capability shall be provided for predicting the position and velocity of the Orbiter or target at some final time in the future or past, when an initial state and time are given.

The Onorbit Precision State Prediction principal function shall make no use of the IMU accumulated sensed velocities and therefore is a free-flight prediction process even though it may be performed during periods of flight in which navigation is using accumulated sensed velocities.

Since this principal function shall be used for different purposes having different environmental requirements in various navigation phases, the user shall, by setting the control flags to the appropriate values and by choosing the prediction method or integration step size, have the option to trade off the accuracy of the integration and the fidelity of the mathematical models in favor of the shorter execution time. This is accomplished with parameters specified prior to the invoking of the Onorbit Precision State Prediction principal function.

Table 4.3-1 is the principal function input and output list and shows data flow between the Onorbit Precision State Prediction principal function and other principal functions.

This principal function, which provides for Onorbit precision state prediction and rapid state prediction of the Orbiter or target position and velocity states, shall use either a fourth-order Runge-Kutta numerical integration technique, modified with Gill's coefficients, or a single-step two-body method (rapid state prediction). The S. Pines formulation of the equations of motion shall be used with each technique. Detailed requirements for the Runge-Kutta-Gill integration technique and the Pines formulation are provided in sections 4.3.1 and 4.3.2. Noncentral body accelerations shall be generated by the user-selected acceleration models (section 4.2.4.1.1) to account for perturbations due to drag, venting and uncoupled thrusting, and variations in the Earth's gravitational potential.

A. Detailed Requirements.— The Onorbit Precision State Prediction principal function computational scheme shall be performed as follows:

1. The desired gravity (GMDP and GMOP), drag (DMP), venting and uncoupled thrusting (VMP), and vehicle-attitude (ATMP) mode flags shall be obtained from the user, together with the prediction integration step size (PRED_STEP), initial state and time (R_PRED_INIT, V_PRED_INIT, and T_PRED_INIT), and final time at the end of the prediction interval (T_PRED_FINAL). If prediction is being performed for the Orbiter (i.e., ATMP = 1), the Orbiter mass to be used during prediction shall be user specified (PRED_ORB_MASS) along with an Orbiter reference area (PRED_ORB_AREA) and drag coefficient (PRED_ORB_CD).

The initial state vector shall then be renamed for use in the Pines equations-of-motion formulation and the seventh variable of integration (XN₇) initialized to zero:

XN₁ to 3 = R_PRED_INIT

XN₄ to 6 = V_PRED_INIT

XN₇ = 0.

In the above equations, the seventh variable of integration (XN₇, required by the Pines technique), is the integrated initial time T_PRED_INIT.

2. A check shall now be made on the gravity mode flag (GMDP) to determine if prediction is to be accomplished through the use of a simple two-body solution of a more precise integration technique.

```

!
! GMDP = 0
!

```

- a. If a two-body solution is required, (i.e., GMDP = 0) the prediction interval is computed as

$i_CUR = T_PRED_FINAL - T_PRED_INIT$

- b. If a more precise integration technique is required (i.e., GMDP ≠ 0), several steps shall be performed to set up parameters required for the integration process.

- (1) The input prediction step (PRED_STEP) is checked against a permission loaded maximum stepsize (DT_MAX) to verify its reasonability:

```

!
! PRED_STEP > DT_MAX
!

```

If the input step is greater than the allowable maximum, then the value is reset to the maximum stepsize pre-mission loaded:

PRED_STEP = DT_MAX

Otherwise, the prediction stepsize input is left unchanged.

- (2) Next, the total prediction time interval is calculated from the input initial and final times, and the current integrator time is set to zero:

$$TIME_DEL = T_PRED_FINAL - T_PRED_INIT$$

$$T_CUR = 0.$$

- (3) If the total prediction time interval, $TIME_DEL$, is less than zero, a backward prediction has been requested and the internal integration step (DT_STEP) is set to a negative value of the input stepsize:

If: $TIME_DEL < 0.$

Then: $DT_STEP = - PRED_STEP$

Otherwise, $TIME_DEL \geq 0.$, the internal prediction step is set to the input prediction step:

$$DT_STEP = PRED_STEP$$

- (4) The actual integration of the Orbiter or target state equations (formulated according to the Pines technique) shall now be performed by proceeding as follows for each step in the integration interval. Note that, in the Pines equations-of-motion formulation, it is the initial conditions (R_PRED_INIT , V_PRED_INIT , and T_PRED_INIT) that are integrated and then used in the closed-form solution of a two-body, unperturbed orbital problem using an F and G series.

The fourth-order Runge-Kutta-Gill integration technique shall be invoked in conjunction with the Pines equation-of-motion formulation for each predictor step (as discussed in section 4.3.1) until the prediction interval has been covered as follows (i.e. until $T_CUR = TIME_DEL$):

DO UNTIL
 $|T_CUR - TIME_DEL|$
 $\leq PRED_TIME_TOL$

- Check, on each step, to determine if the absolute value of the prediction step is greater than the absolute value of the prediction interval remaining;

If,

$$|DT_STEP| > |TIME_DEL - T_CUR|$$
then: $DT_STEP = TIME_DEL - T_CUR$

- The Runge-Kutta-Gill integrator shall then be invoked, with the input or adjusted value of DT_STEP ;

CALL: RK_GILL

IN LIST: \underline{XN} , DT_STEP , T_CUR , $GNOP$, $GMDP$, DMP ,
 VMP , $ATMP$, T_PRED_INIT OUT LIST: \underline{XN} , T_CUR

The output vector (\underline{XN}), are the adjusted initial conditions to be used in the Pines equations of motion for a precision prediction conic solution.

3. After the calculations, as dictated by the testing of step 2, have been performed, the Pines equations of motion will be invoked to solve for the position and velocity vectors corresponding to T_PRED FINAL:

CALL: PINES_METHOD

IN LIST: \underline{XN} , T_CUR , $GNOP$, $GMDP$, DMP , VMP , $ATMP$, T_PRED_INIT OUT LIST: \underline{DERIV} , \underline{X}

4. Upon being calculated (whether by a precise technique or a single step two-body solution), the final position and velocity are renamed for output:

 $\underline{R_PRED_FINAL} = X_1 \text{ to } 3$ $\underline{V_PRED_FINAL} = X_4 \text{ to } 6$

- B. Interface Requirements. - Input and output requirements are contained in table 4.3-2.

- C. Processing Requirements. - This principal function requires user-supplied values of gravity ($GNOP$ and $GMDP$), drag (DMP), venting and uncoupled thrusting (VMP), and vehicle-attitude ($ATMP$) mode flags, in conjunction with the initial state and time ($\underline{R_PRED_INIT}$, $\underline{V_PRED_INIT}$, T_PRED_INIT) and the final time (T_PRED_FINAL). Appropriate acceleration models may be found in section 4.2.4.1.1. When using this function for Orbiter or target vehicle state prediction, the venting and uncoupled thrusting flag (VMP) shall be set to zero. Additionally, if drag modeling is desired for Orbiter or target state prediction, the drag mode flag (DMP) should be set to one and the

attitude mode flag (ATMP) set equal to one for the Orbiter or equal to two for the target. For prediction of the Orbiter's state, an Orbiter reference area (PRED_ORB_AREA), an Orbiter drag coefficient (PRED_ORB_CD), and an Orbiter mass (PRED_ORB_MASS) are also to be supplied. The Onorbit Precision State Prediction principal function is called by the following modules in the Onorbit/Rendezvous Navigation Sequencer principal function:

OPS 2 OR 8 INITIALIZE
STATE_VECTOR_PREDICT_TASK

and by the following module in the Onorbit/Rendezvous Navigation principal function:

STATE_VECTOR_PREDICT_TASK

In addition it may be called by other users outside of navigation.

- D. Constraints.-- Vent thrust is not to be modeled in prediction. Hence, the vent thrust flag (VMP) is to be set to zero. Atmospheric drag is to be modeled with constant coefficients. Hence, whenever drag is to be modeled in a prediction, the vehicle attitude flag (ATMP) is not to be set to zero (see section 4.2.4.1.1).

Since the same compool locations are used by all users of this principal function for setup and output, it is required that these parameters be protected from alteration by other users during execution of this principal function. Variables to be protected are listed as follows: GMOP, GMDP, DMP, VMP, ATMP, PRED_STEP, R_PRED_INIT, V_PRED_INIT, T_PRED_INIT, R_PRED_FINAL, V_PRED_FINAL, T_PRED_FINAL, PRED_ORB_AREA, PRED_ORB_CD, PRED_ORB_MASS.

- E. Supplementary Information.-- The Onorbit Precision State Prediction principal function shall be used for both precision and rapid state prediction. Rapid state prediction consists of a less accurate, single-step two-body F and G series solution involving no numerical integration. Table 4.3-3 lists several examples of input variable list combinations for the various types of prediction performed. A suggested implementation of this principal function may be found in Appendix C under the following:

Orbiter	Rapid two-body	0	0	0	0	0	0	Single-step two-body F and G series solution.
Target	Precision	4	4	1	0	2	User selects	Full fourth degree potential model drag with constant area, drag coefficient.
Target	Rapid precision	2	0	1	0	2	User selects	J ₂ only potential model with constant drag coefficient, area.
Target	Rapid two-body	0	0	0	0	0	0	Single-step two-body F and G series solution.

*When prediction is being performed for both vehicles (Orbiter and target) over a similar trajectory, the same degree and order potential model should be used for each prediction so that potential model errors will be avoided.

4.3.1 Integration of the Equations of Motion (RK_GILL)

A fourth-order Runge-Kutta-Gill integration technique is used for prediction of the Orbiter and target state vectors. The technique is actually a fourth-order Runge-Kutta numerical integration technique, modified with Gill's coefficients, used in conjunction with S. Pines' formulation for the equations of motion (see section 4.3.2).

- A. Detailed Requirements.- The Runge-Kutta-Gill (RK_GILL) integration subfunction will be activated each time a call statement of the following form is encountered:

CALL: RK_GILL

IN LIST: XN,DT_STEP, T_CUR,GMO,GMD,DM,VM,ATM,T_IN

OUT LIST: XN,T_CUR

where:

XN = an array containing the seven variables of integration (i.e., integrated initial conditions)
 DT_STEP = the integration step size
 T_CUR = the RK_GILL step size subinterval time (i.e., there are four cycles of RK_GILL per integration step size)
 GMO = the Earth gravitational potential model order
 GMD = the Earth gravitational potential model degree
 DM = the drag acceleration model flag
 VM = the vent and uncoupled thrust acceleration model flag
 ATM = the vehicle attitude mode flag
 T_IN = the initial state time

The computations initiated by call to the Runge-Kutta-Gill subfunction will be the following and in the order indicated.

1. The initial time of the current integration step, T_CUR, shall be saved in T_STOR.

T_STOR = T_CUR

2. Next a counter, J, shall be tested to ensure that four evaluations of Runge-Kutta-Gill are determined.

```

DO FOR
  J = 1
  TO 4
  
```

- a. If the evaluation cycle is 4 or less, a new value of T_CUR (the integration step time) shall be determined as:

$$T_CUR = T_STOR + AA_J \quad BB_J \quad DT_STEP$$

- b. Next the Pines method will be called to calculate derivatives ($DERIV$), of the initial conditions.

CALL: PINES_METHOD

IN LIST: XN , T_CUR , GMO , GMD , DM , VM , ATM , T_IN

OUT LIST: $DERIV$, X

The call arguments are as previously described, and details of the Pines method are given in section 4.3.2.

- c. The Runge-Kutta-Gill integration continues with the numerical integration of derivatives of the initial conditions (XN_L) in the following manner:

where:

AA , BB , CC , DD = premission-loaded arrays ($J = 1$ to 4) containing coefficients required for this formulation of the Runge-Kutta-Gill integration technique

XN = an array containing the seven variables of integration (i.e., integrated initial conditions)

$DERIV$ = an array containing the total derivatives of the initial conditions at the current time

P = integration variable used in Runge-Kutta-Gill technique

Q_L = integration variable used in the Runge-Kutta-Gill technique

After the seven variables of integration have been obtained, the RK GILL will return to repeat step 2, and cycle through until J is greater than 4.

- B. Interface Requirements.-- Input and output parameters for the Runge-Kutta-Gill integration subfunction are given in table 4.3.1.
- C. Processing Requirements.-- The Runge-Kutta-Gill subfunction is called by
Onorbit precision state prediction (ONORBIT_PREDICT)
- D. Constraints.-- Because the Runge-Kutta-Gill subfunction is used by precision prediction subfunctions which may be executed by multiple users at the same time, it should be protected against interruption.
- E. Supplementary Information.-- A suggested implementation of this subfunction in the form of detailed flow diagrams may be found in Appendix C under the following:

4.3.2 Equations of motion (PINES_METHOD)

For predicting the Orbiter and target state vectors, the equations of motion are to take the form of a variation-of-parameters method devised by S. Pineas, where parameters to be varied are the Cartesian initial conditions of the motion. The integration scheme to be used in connection with these equations is the Gill modification of the Runge-Kutta technique (see section 4.3.1).

- A. Detailed Requirements.-- The Pineas equations of motion subfunction will be invoked whenever a call statement of the following form is encountered:

CALL: PINES_METHOD

IN LIST: XN, T_CUR, GMD, GMD, DM, VM, ATM, T_IN

OUT LIST: DERIV, X

where:

XN = the seven variables of integration

T_CUR = the initial integration time of the current step

GMD = Earth's gravitational potential model order

GMD = Earth's gravitational potential model degree

DM = drag model acceleration computation flag

VM = vent and thrusting acceleration model flag

ATM = attitude mode flag

T_IN = initial time

and:

DERIV = the output total derivatives of integration

X = output two body position and velocity vectors
of conic

The PINES_METHOD subfunction will cause the following calculations to be made in the order given:

1. Several terms used in the F and G series calculations for the closed-form two-body equations are computed.

$$R_IN = | XN_1 \text{ to } 3 |$$

$$R_IN_INV = 1./R_IN \quad F3$$

$$SMA = 1./(2. R_IN_INV - (XN_4 \text{ to } 6 \cdot XN_4 \text{ to } 6)/EARTH_MU) \quad F3$$

$$C1 = SQRT (SMA)/SQR_EMU \quad F3$$

F4

$$DELTAT = T_CUR - XN_7$$

$$D_IN = XN_1 \text{ to } 3 \cdot XN_4 \text{ to } 6$$

$$R_FIN_TEMP_INV = 0.$$

2. The conic solution subfunction (F_AND_G) shall then be invoked to calculate several terms used in computation of the conic velocity vector (X_4 to 6) and initial condition derivatives and compute the two-body conic position vector (X_1 to 3) as follows (see section 4.2.5.2.1).

CALL: F_AND_G

IN LIST: SMA, DELTAT, C1, XN_1 to 3, R_IN_INV, R_FIN_TEMP_INV, XN_4 to 6, D_IN, D_FIN_TEMP

OUT LIST: F, G, FDOT, GDOT, S0, S1, S2, S3, X_1 to 3, R_FIN_INV, THETA

3. The two-body velocity vector shall then be computed:

$$X_4 \text{ to } 6 = FDOT XN_1 \text{ to } 3 + GDOT XN_4 \text{ to } 6$$

4. Perturbation accelerations shall now be calculated and several computations shall then be performed to compute perturbation derivatives for F and G series terms used in calculating total derivatives of the seven variables of integration.

$$T_ACCEL = T_IN + T_CUR$$

$$P = ACCEL_ONORBIT (GMD, GMO, DM, VM, ATM, X_1 \text{ to } 3, X_4 \text{ to } 6, T_ACCEL)$$

$$P = P - G_CENTRAL$$

$$D_TAU = X_1 \text{ to } 3 \cdot P$$

$$D_AUX = X_4 \text{ to } 6 \cdot P$$

$$C2 = C1^2$$

F3 This equation shall be protected against division by zero (Reference 3.6-3).

F4 This equation shall be protected against square roots of a negative number (Reference 3.6-4).

$$S1 = C1 S1$$

$$S2 = C2 S2$$

$$C3 = 1./C2$$

F3

$$S3 = SMA S2$$

$$S4 = 2. S3 D_AUX$$

$$C4 = C2 D_AUX$$

$$C5 = C4 S1$$

$$S5 = S2 D_TAU$$

$$DD = S1 C3 R_IN (SMA R_IN_INV-1.) + S0 D_IN$$

$$S6 = 2. S2 C4 DD + S5$$

$$R_IN_TAU = S4 - C2 S1 D_AUX DD - S1 D_TAU$$

$$R_IN_AUX = R_IN_INV R_IN_TAU$$

$$F_TAU = (S3 C3 R_IN_AUX - S4) R_IN_INV$$

$$Q_TAU = C5/R_FIN_INV - S6$$

F3

$$FD_TAU = FDOT (C4 - R_IN_AUX)$$

$$GD_TAU = - S4 R_FIN_INV$$

5. Finally, the total derivatives of the variables of integration are to be computed as follows:

$$DERIV_1 \text{ to } 3 = GD_TAU X_1 \text{ to } 3 - Q_TAU X_4 \text{ to } 6 - Q P$$

$$DERIV_4 \text{ to } 6 = - FD_TAU X_1 \text{ to } 3 + F_TAU X_4 \text{ to } 6 + F P$$

$$DERIV_7 = S6 - 3. C4 SMA (C1 THETA-S1) - C5/R_FIN_INV \quad F3$$

- B. Interface Requirements.- Input and output for the Pines method subfunction are given in table 4.3.2.
- C. Processing Requirements.- The following is a list of subfunctions and principal functions that call the Pines method.

RK_GILL
ONORBIT_PREDICT

F3 This equation shall be protected against division by zero (Reference 3.6-3).

- D. Constraints. - The ACCEL_ONORBIT function shall not be invoked by any other software module during the computation of the perturbation acceleration vector, P, to maintain the correct value of the central force term, G _ CENTRAL.
- E. Supplementary Information. - A suggested implementation of the Pines method of the equations of motion in the form of detailed flowcharts may be found in Appendix C under the following:

4.4 ONORBIT/RENDEZVOUS USER PARAMETER PROCESSING SEQUENCER PRINCIPAL FUNCTION (ONORBIT_REND_UPP_SEQ)

This principal function will provide a capability for initialization and control of the principal functions and subfunctions associated with the computations of user parameters during the onorbit/rendezvous operational sequence. This sequencer will provide initialization and control of the onorbit user parameter state propagation subfunction and those user parameter processing principal functions used for this operational sequence.

Events to be used as cues by the sequencer for performing the required initialization and sequencing are defined in the Level B GN&C CPDS. The particular events and a summary of the associated user parameter actions pertaining to this user parameter sequencer are given in table 4.4-1.

A. Detailed Requirements. - The Onorbit/Rendezvous User Parameter Processing Sequencer will be initiated upon the occurrence of any of the following events:

- Major mode transition from 106 to 201
- Major mode transition from 301 to 201
- Transition from OPS 2 to OPS 8
- Transition from OPS 00 to Major Mode 201
- Transition from OPS 8 to Major Mode 201

This sequencer shall be terminated upon the transition from OPS 2 or OPS 8 to OPS 3 or OPS 00.

The following paragraphs specify the detailed requirements that are summarized in table 4.4-1. These requirements specify, for each of the event cues to be utilized by the sequencer, the actions that the sequencer is to initiate.

- EVENT_60A; transition from OPS 8 to OPS 2
- EVENT_60B; transition from OPS 2 to OPS 8

- a. If any of the above event flags has been set to "ON" by Moding, Sequencing, and Control (MSC), or crew input and detected "ON" by

79FM10

this sequencer, a check shall be made on a flag set by the Onorbit/
Rendezvous Navigation Sequencer:

OPS_2_OR_8_INITIALIZE_
COMPLETE - ON

TABLE 4.4-1.- ONORBIT/RENDEZVOUS USER PARAMETER PROCESSING SEQUENCER EVENTS

Event No.	Event Name/Description	Action Taken by Sequencer in Response to Event
60	Transition from OPS 1 to OPS 2	Initiate cyclic execution of onorbit user parameter state propagation and onorbit user parameter calculations at a repetition rate of 0.52 Hertz
E1	Transition from 301 to 201	Same as Event 60 action
84	Transition from OPS 00 to 201	Same as Event 60 action
60A	Transition from OPS 8 to 201	Same as Event 60 action
73	Transition from 202 to 201	Cancel and reschedule the onorbit user parameter state propagation to change the cyclic repetition rate of onorbit user parameter state propagation to repetition rate of 0.52 Hertz.
69	Initiate guidance	Cancel onorbit user parameter state propagation. Reschedule cyclic processing of onorbit user parameter state propagation at a repetition rate of 1.04 Hertz
60B	Transition from 201 to OPS 8	Same as Event 60 action

This signal (=ON) indicates that the necessary initialization of certain state parameters has been accomplished within the Onorbit/Rendezvous Navigation Sequencer (section 4.1) and that the onorbit/rendezvous user parameter state propagation and onorbit user parameter calculations subfunctions shall commence at a repetition rate of 0.52 Hertz.

2. Next, a check shall be made to detect a transition from Major Mode 202 to 201; EVENT_73. Based upon this cue, execution of the onorbit user parameter state propagator shall be cancelled and rescheduled at a rate of 0.52 Hertz.
 3. A check shall now be made on the EVENT_69 cue (initiate guidance). Based upon this cue, the current scheduling of the user parameter state propagator is to be cancelled. Cyclic execution of this task is to be rescheduled at a repetition rate of 1.04 Hertz beginning with this event. The purpose of cancelling and rescheduling the onorbit user parameter state propagator upon the initiate guidance signal is to not only change the execution rate, but to also get the execution of this module in synchronization with the execution of onorbit guidance, which is to be initiated at this time. This cancelling and rescheduling is to be done "y" seconds prior to OMS ignition, such that a subsequent user state update will occur, as nearly as possible, at the time of ignition.
- B. Interface Requirements.-- Input and output requirements for this principal function are presented in table 4.4-2.
- C. Processing Requirements.-- None
- D. Constraints.-- None
- E. Supplemental Information.-- A suggested implementation of the onorbit/rendezvous UPP sequencer in the form of detailed flow charts is shown in Appendix D under ONORBIT_REND_UPP_SEQ.

1.5 USER PARAMETER PROCESSING PRINCIPAL FUNCTION

This principal function shall serve as the interface between navigation and users of navigation-related data during the onorbit operational sequence. This function shall maintain the vehicle state within the user parameter state propagation subfunction and shall:

- Provide this state to users who require vehicle state parameters in M50 coordinates (see User Parameter State Propagation, section 4.5.1 and Onorbit User Parameter Calculations, section 4.5.2).
- Provide the software to transform this state for users who require nav state-related parameters (see User Parameter Calculations, section 4.5.2).

Interface parameters between this principal function and other GN&C principal functions are presented in table 4.5.

4.5.1 User Parameter State Propagation (ONORBIT_REND_USER_PARAM_STATE_PROP)

The onorbit and rendezvous navigation state propagation subfunctions advance the navigation state vector at relatively large intervals, at the end of which external measurement data processed by the filter are incorporated when appropriate. Users, such as guidance and displays, require a knowledge of the state vector at shorter intervals. The onorbit and rendezvous user parameter state propagation subfunction will satisfy the requirements of such users by integrating the equations of motion within the intervals of the navigation propagation with use of a simplified computation of the gravitational acceleration in conjunction with a small step size.

The integration of the Orbiter and target state vectors is to be performed by an average-g process, using a modeled acceleration that contains a simplified Earth gravitational force model. In the case of the Orbiter, if the acceleration derived in the UPP state propagator from the IMU sensed velocities is above a certain threshold level, this acceleration is to be used in the integration process. If the sensed acceleration falls below the threshold level, only the modeled acceleration is to be utilized in the integration.

In the rendezvous phases it is also necessary to propagate the target vehicle state. There being no IMU's in this vehicle, only the modeled acceleration is to be used in the integration.

This process will be restarted after each filter update with the filter states. The values of the filter updated position and velocity vectors, together with their time tag and the total accumulated IMU velocity, are stored (at each navigation cycle) in special locations for use by the user parameter state propagation subfunction. This prevents the errors resulting from use of a less accurate integrating scheme from becoming too large and, at the same time, provides a synchronization between the propagation tasks.

- A. Detailed Requirements.- A capability shall be provided for a fast computation of the position and velocity of the Orbiter during all phases of OPS 2 and OPS 8, and of the position and velocity of the target vehicle during all rendezvous phases OPS 2. This computation shall provide the required state vectors in an M50 coordinate system by the integration of the equations of motion that include gravity accelerations and, for the Orbiter, the IMU sensed velocities, if they give a significant contribution.

The following steps shall be performed (in the order indicated):

1. Snap the IMU accumulated sensed velocity and time tag:

SNAP(V_IMU_SNAP ,T_IMU)

(see section 4.2.2.1)

2. In the case of the Orbiter, the value of the state that is to be advanced (integrated forward in time) may be from one of two sources (the one used depends on the tested value of the flag (FILT_UPDATE), which indicates the availability of a filter updated state):
- a. If an update from the filter is available (FILT_UPDATE = ON), the navigation filter updated state, together with its time tag and associated IMU accumulated sensed velocity, is to replace the previous propagated state, time tag, and accumulated velocity. The filter updated values are R_RESET, V_RESET, T_RESET and V_IMU_RESET; the vectors maintained by the user parameter state propagator are R_AVGG and V_AVGG. The time tag is T_STATE. Thus, if FILT_UPDATE = ON, the following will be done:

$$\underline{R_AVGG} = \underline{R_RESET}$$

$$\underline{V_AVGG} = \underline{V_RESET}$$

$$\underline{V_IMU_OLD} = \underline{V_IMU_RESET}$$

$$\underline{T_STATE} = \underline{T_RESET}$$

- b. If an update from the filter is not available (FILT_UPDATE = OFF), the propagated state, saved from the previous cycle, is to be advanced. The value of the IMU-accumulated sensed velocity saved from the previous cycle is available for state advancement purposes.
3. Compute the interval over which advancement is required:

$$DT_IMU = T_IMU - T_STATE$$

interval ($\underline{DT_IMU}$).

$$DA_THRESHOLD_IMU = IMU_NAV_ACCEL_THRESH$$

$$(GO \ 10^{-6}) / DT_IMU$$

F3

F3 This equation shall be protected against division by zero (Reference 3.6-3).

- (3) Test the magnitude of the sensed acceleration ($|A_SENSED|$) for this UPP cycle against the computed IMU threshold.

$|A_SENSED| > DA_THRESHOLD_IMU$

If $|A_SENSED| > DA_THRESHOLD_IMU$, set a flag to ON for telemetry

UPP_USE_IMU_DATA = ON

Otherwise, turn the telemetry flag OFF, and set the acceleration value to zero.

UPP_USE_IMU_DATA = OFF

$A_SENSED = 0.$

- b. If the PWRD_FLT_NAV flag is OFF, turn the telemetry flag to OFF, and set the acceleration value to zero.

UPP_USE_IMU_DATA = OFF

$A_SENSED = 0.$

5. The position and velocity vectors of the Orbiter shall then be obtained by a call to the user parameter state integrator (see section 4.5.1.1).

CALL: AVERAGE_G_INTEGRATOR

IN LIST: R_AVGG, V_AVGG, DT_IMU, A_SENSED, T_STATE, T_IMU

OUT LIST: R_AVGG, V_AVGG

The calculations performed up to this point refer to the Orbiter's state. Propagation of the target state is required only during the rendezvous phases. A flag (DOING_REND_NAV), which has the value ON only during these phases, shall then be consulted by the user parameters state propagator.

6. Test the DOING_REND_NAV flag. If it is found to be ON, perform the following steps:

- a. Test the FILT_UPDATE flag to determine if a target state is available from NAV.

If FILT_UPDATE = ON, set

R_TARGET = R_TV_RESET

V_TARGET = V_TV_RESET

where R_TARGET and V_TARGET represent the position and velocity vectors of the target vehicle advanced by the user parameter state propagator, and R_TV_RESET and V_TV_RESET represent the target state vectors from the navigation filter.

- b. Advance the target state by a call to the integrator. In this call, the vector that contains the sensed acceleration shall be set to zero.

A_SENSED = 0

CALL: AVERAGE_G_INTEGRATOR

IN LIST: R_TARGET, V_TARGET, DT_IMU, A_SENSED, T_STATE, T_IMU

OUT LIST: R_TARGET, V_TARGET
(see section 4.5.1.1)

After the state vector updates have been completed, the following steps are to be executed:

7. Save the time tag output for use in the next cycle:

T_STATE = T_IMU

8. Save the latest IMU accumulated sensed velocity:

V_IMU_OLD = V_IMU_SNAP

9. Set the FILT_UPDATE flag to OFF.

This completes the sequence of calculations of a user parameter state propagation cycle.

- B. Interface Requirements.-- The input and output variables are listed in table 4.5.1.
- C. Processing Requirements.-- None
- D. Constraints.-- None
- E. Supplementary Information.-- A suggested implementation in the form of a detailed flowchart is found in Appendix D under the name ONORBIT_REND_USER_PARAM_STATE_PROP.

4.5.1.1 Integration (AVERAGE_G_INTEGRATOR)

The integration subfunction is called by the user parameter state propagation subfunction to propagate the Shuttle and target state vectors to current time.

- A. Detailed Requirements.— This subfunction is called with the following internal variables in the IN LIST and OUT LIST:

IN LIST: R_AV, V_AV, DTIME, AC, T_STATE, T_IMU

OUT LIST: R_AV, V_AV

where

R_AV } user parameter state vector
V_AV }

DTIME interval to propagate state vector over

AC acceleration vector

T_STATE user parameter time tag

T_IMU current time

The following steps shall be performed (in the order indicated);

1. By means of a call to the acceleration function, compute the gravitational acceleration for the input state vector and corresponding time tag (see section 4.2.4.1.1):

$$GR = ACCEL_ONORBIT (GM_DEG_LOW, GM_ORD_LOW, DFL_AVG, VFLTV_PRED, ATFL_OV, \underline{R_AV}, \underline{V_AV}, T_STATE)$$

2. Advance the position vector by the average-g method:

$$\underline{R_AV} = \underline{R_AV} + DTIME (\underline{V_AV} + .5 DTIME (\underline{AC} + GR))$$

3. Use this updated position vector and the current time to find a new value of the gravitational acceleration (see section 4.2.4.1.1):

$$GR1 = ACCEL_ONORBIT (GM_DEG_LOW, GM_ORD_LOW, DFL_AVG, VFLTV_PRED, ATFL_OV, \underline{R_AV}, \underline{V_AV}, T_IMU)$$

4. Advance the velocity vector by the average-g method:

$$\underline{V_AV} = \underline{V_AV} + DTIME (\underline{AC} + .5 (GR + GR1))$$

The quantities GM_DEG_LOW, GM_ORD_LOW, VFLTV_PRED, DFL_AVG, and ATFL_OV are pad-loaded values of the various acceleration constants, designed for high usage rates (see section 4.7 for values).

- B. Interface Requirements. - The input and output variables are listed in table 4.5.1.1.
- C. Processing Requirements. - None
- D. Constraints. - None
- E. Supplementary Information. - A suggested implementation in the form of a detailed flow chart is found in Appendix D under the name

AVERAGE_G_INTEGRATOR.

4.5.2 Onorbit User Parameter Calculations (ONORBIT_USER_PARAMETER_CALCULATIONS)

This subfunction contains software to compute quantities required by the GN&C/SM-PL interface and the universal pointing principal function. These calculations are required during OPS 2.

A. Detailed Requirements. - The following steps shall be performed (in the order indicated):

1. If the rendezvous nav flag is set on (DOING_REND_NAV = ON), the delta position and velocity vectors in the M50 system are computed. These vectors represent position and velocity vectors from the Shuttle to the rendezvous target.

$$\underline{DEL_R_TARG} = \underline{R_TARGET} - \underline{R_AVGG}$$

$$\underline{DEL_V_TARG} = \underline{V_TARGET} - \underline{V_AVGG}$$

2. The M50 to Greenwich-true-of-date transformation matrix is computed at the time of the state vectors, T_STATE.

$$\underline{M50_TO_EF} = \underline{EARTH_FIXED_TO_M50_COORD}(T_STATE)^T$$

3. The Shuttle state vector ($\underline{R_AVGG}$, $\underline{V_AVGG}$) is transformed into the Greenwich-true-of-date, and the Earth's rotational effects are added to the X and Y components to yield the Earth-relative velocity vector.

$$\underline{R_EF} = \underline{M50_TO_EF} \underline{R_AVGG}$$

$$\underline{V_EF} = \underline{M50_TO_EF} \underline{V_AVGG}$$

$$\underline{V_RHO_EF1} = \underline{V_EF1} + \underline{EARTH_RATE} \underline{R_EF2}$$

$$\underline{V_RHO_EF2} = \underline{V_EF2} - \underline{EARTH_RATE} \underline{R_EF1}$$

$$\underline{V_RHO_EF3} = \underline{V_EF3}$$

4. The Greenwich mean time associated with the position and velocity vectors is then saved:

$$\underline{T_SEC_GMT} = \underline{T_STATE}$$

B. Interface Requirements. - Input and output parameters for this subfunction are shown in table 4.5.2.

C. Processing Requirements. - Processing requirements for this subfunction are specified in the ONORBIT_REND_UPP_SEQUENCER.

D. Constraints. - None

- E. Supplemental Information.-- A suggested implementation in the form of a detailed flowchart can be found in Appendix D under the name:

† Value returned from the function

4.6 LANDING SITE UPDATE PRINCIPAL FUNCTION (LANDING_SITE_UPDATE_PRINCIPAL_FUNCTION)

This function provides the capability to reconfigure the dynamic parameters pertaining to the runway and TACAN sites, which are to carry over into OPS 3 for use during the deorbit through landing operational sequence. This section describes the software processing for data transfer from maxi to mini tables for runway and TACAN parameters. Output from this function is via the OPS 2 data list. The requirements of this function are to give the crew specific control via keyboard input to:

- Effect a maxi to mini table transfer of runway data (including MSBLS where available) and the TACAN's appropriate for the primary runway selection.
- View the current (latest) choice of runway identifying parameters on the orbit OPS display.
- Provide the current mini table data at the end of OPS 2 to be available for use in OPS 3. If this function is not executed in OPS 2, the I-Loaded mini tables contain default values appropriate for nominal end of mission use in OPS 3.

The guidance targeting uplink OPS formats (PEG 4 and PEG 7) also contain parameters identifying a request for maxi to mini data transfer. Thus the appropriate uplink processors may also invoke this process and provide the necessary input data.

- A. Detailed Requirements. - The landing site update principal function may be invoked during OPS 2 by the universal pointing display function. This function may be performed whenever the OPS display is active and will respond to crew input from the keyboard. This function may also be invoked by the uplink processors for the PEG 4 and PEG 7 command uplink.

The principal function requires two tables in memory for both runways and TACAN:

- Runway and TACAN maxi tables
- Runway and TACAN mini tables

The runway maxi table consists of data sets for 18 runways and 4 MSBLS to support contingency landing sites which are grouped by geographic location.

Runway Maxi Table

<u>Runways</u>	<u>MSBLS*</u>	<u>Geographic Locations</u>
1-3	1-2	A
4-6	3-4	B
(7-8)		(C)
(9-10)		(D)
(11-12)		(E)
(13-14)		(F)
(15-16)		(G)
(17-18)		(H)

The runway mini table contains data for three runways and two MSBLS installations. The data in this table is normally I-Loaded to support the nominal end of mission (OPS-3); however, these data may be overwritten by invoking the principal function to transfer contingency site data. The mini table is considered to consist of runways 19, 20 and 21 initially, that is:

Runway Mini Table

<u>Runway No</u>	<u>Runway Designation</u>
19 **	PRIMARY (Runway and associated MSBLS site data)
20	SECONDARY (Runway and associated MSBLS site data)
21	ALTERNATE (Runway site data)

The parameters PRI_MAXI_CURRENT, SEC_MAXI_CURRENT, and ALT_MAXI_CURRENT are used to specify which of the maxi table runways have been transferred to the respective mini table locations. Prior to any such transfer, the parameters should be initialized to the values 19, 20, and 21, respectively, to indicate that the I-Loaded mini table values are current and have not been overwritten. Following any transfer of data, the appropriate parameters will be updated to identify the current contents in the runway mini table. These three parameters are output to the universal pointing display.

The runway tables consist of data sets of the following parameters:

Geodetic latitude
 Longitude
 Runway azimuth
 Altitude above reference ellipsoid
 4h for MSL at runway site (from reference ellipsoid)
 Magnetic variation
 Runway name (six character string; example: EDW17)
 MLS_AVAIL (primary and secondary runways only)

- * MSBLS installations are available for runways 1, 2, 4 and 5.
 ** For any of these initial contents which are overwritten, it may thereafter consist only of runway number 1 to 18.

The following parameters are associated with available MSBLS SITES; i.e., for runways in maxi table slots 1, 2, 4, and 5 and for the I-Loaded mini table runways designated PRIMARY and SECONDARY.

LAT_MLS_R_AZ
 LONG_MLS_R_AZ
 ALT_MLS_R_AZ
 R_AZ_SCANNER_BEARING
 LAT_MLSEL
 LONG_MLSEL
 ALT_MLSEL
 EL_SCANNER_BEARING
 BIAS_MLS_RANGE
 BIAS_AZMLS
 BIAS_ELMLS
 X_DMEAZ_RW
 X_EL_RW
 Y_DMEAZ_RW

The TACAN maxi table consists of 50 TACAN's grouped according to proximity to the approach path to landing at a particular runway site; they are grouped as follows:

<u>TACAN</u>	<u>Runway Geographic Location</u>
--------------	-----------------------------------

1-10	A
11-20	B
(21-25)	(C)
(26-30)	(D)
(31-35)	(E)
(36-40)	(F)
(41-45)	(G)
(46-50)	(H)

The TACAN mini table is I-Loaded to support the initial (I-Load) mini table runways, but it shall be reconstructed automatically by a transfer of a maxi table runway to the mini table primary runway. For example, if any maxi table runway in geographic area B is transferred to the mini table primary runway, then the TACAN's for area B (# 11-20) will also be transferred to the TACAN mini table.

The TACAN tables contain the following data for each TACAN site:

TACAN channel number	{Positive for X-mode}
	{Negative for Y-mode}
Geodetic latitude	
Longitude	
Height above reference ellipsoid	
Δh for MSL correction at TACAN site	
Magnetic variation	

TACAN bearing bias *
TACAN range bias *

The runway maxi table to mini table transfer is performed on demand and expects one or more of the discretes, ITEM1_IN, ITEM2_IN, or ITEM3_IN to be ON. If ITEM1_IN (primary runway) or ITEM2_IN (secondary runway) is set to ON, both runway site data and the corresponding MSBS site data (if available, that is, for choice of runway = 1, 2, 4, or 5) from the maxi table is to be loaded into the primary or secondary data locations, respectively, within the mini table. If ITEM3_IN (alternate runway) is set to ON, only runway site data are to be loaded into the alternate runway data locations within the mini table. The integers PRI_MAXI_SELECT, SEC_MAXI_SELECT, and ALT_MAXI_SELECT indicate which data set within the maxi table is to be transferred to the corresponding data set within the mini table. After performing the data transfer, the appropriate ITEM1_IN, ITEM2_IN, or ITEM3_IN is set to ON for output.

Whenever the primary runway data has been altered by a maxi to mini data transfer, TACAN data are to be automatically transferred from the maxi TACAN table to the mini TACAN table according to the primary runway's geographic location; specifically, if ITEM1_IN is "ON" and PRI_MAXI_SELECT has a value of 1, 2, or 3, then TACAN data sets 1-10 from the maxi TACAN table are to be transferred to the mini table. Likewise, if PRI_MAXI_SELECT has a value of 4, 5, or 6, then TACAN data sets 11-20 from the maxi TACAN table are to be transferred to the mini table. Finally, whenever PRI_MAXI_SELECT is 7 through 10, or 11 through 14, or 15 through 18, TACAN data sets 21-30 or 31-40 or 41-50, respectively, from the maxi table are to be transferred to the mini table. Note that transfer into secondary or alternate mini table runway slots does not cause additional TACAN transfers; this is operationally redundant.

The ORBIT OPS display also provides additional identification of the mini table contents. That is, it displays RUNWAY_NAME_PSL, RUNWAY_NAME_SSL, and RUNWAY_NAME_ASX, which are contained in the runway mini table. These parameters consists of 6 characters - three letters and two numbers and a blank - e.g: KSC15 or KSC33 for the RTLS runways at KSC.

- B. Interface Requirements.- The initial values of data for the landing site and TACAN minitables are defined in the I-load by the parameter names given in table 4.6-1 (left-most column); normally these data are provided to support the nominal end of mission for the entry through landing in OPS 3. The parameter names for the minitables configured in this OPS for use in OPS 3 are given also in table 4.6-1 (right-most column). It is only these latter minitables (right-most column) which may be updated by the maxi to mini transfers, or uplink, for use in OPS 3, while the I-load parameters (left-most column) are preserved for subsequent transitions into OPS 2. Therefore, for certain transitions into OPS 2, it may be necessary to ensure that those

*Contained only in the mini table; assumed equal to zero for maxi table TACANs.

parameters in the right-hand column are initialized with the I-load values, while for other transitions into OPS 2 reinitialization must be avoided. Specific conditions for these initializations are given in paragraph C, Processing Requirements.

The maxitables are I-loaded with the parameter names which are used by the software; therefore, they are always initialized by the I-load values whenever OPS 2 is entered.

The inputs and outputs for this function are shown in table 4.6-2. The maxitables (4.6-2, Inputs) are initialized directly by I-loads, but may be updated by uplink. The minitables (4.6-2, Outputs) may (depending on previous OPS) be initialized by I-load, may be updated by uplink, and may be updated by this spec function.

The maxitable locations of the current primary, secondary, and alternate runways selected are initialized to 19, 20, and 21 (parameters PRI_MAXI_CURRENT, SEC_MAXI_CURRENT, and ALT_MAXI_CURRENT, respectively). The I-load parameters interface is shown in table 4.6-1 and table 4.6-3.

- C. Processing Requirements.-- As stated in paragraph B, it was necessary to determine whether the minitables which are reconfigured in this OPS (OPS 2) are to be initialized to the values provided by the I-load, or whether values from the previous OPS should be retained. If the transition into OPS 2 is from either OPS 1 or OPS 3, then the I-load values are to be used; but if the transition into OPS 2 is from any OPS other than OPS 1 or OPS 3, the values from that preceding OPS should be retained.

It is not intended that this spec function be invoked for a nominal mission; therefore, the orbit OPS display should show current values prior to execution of this spec. The minitable carried across the OPS 2 to OPS 3 transition should contain the I-loaded data if the spec is not invoked and an uplink has not occurred; it should contain the current reconfiguration data if the spec had been invoked or an uplink had occurred.

- D. Constraints.-- Any initializations that may be required by the implementation of paragraph C to provide the appropriate data for the interface tables of paragraph B must precede the execution of this spec function, precede uplink to the minitables, precede the use of outputs from this function, and precede the transition out of OPS 2. Because outputs support the orbit OPS display, it is recommended that any special processing required be accomplished at the beginning of the OPS 2.
- E. Supplementary Information.-- The flight software I-load contains three minitables of Runway and TACAN site data:

One table appropriate for RTLS (used in OPS 1/6).

One table appropriate for AOA (used in OPS 3, but only when OPS 3 is entered from OPS 1).

One table appropriate for End of Mission (used in OPS 3, but initialized in OPS 2 for nominal End of Mission). The End of Mission table may be reconfigured during OPS 2 via maxi mini transfers and/or uplink with several alternate data sets; the reconfigured tables should be used in OPS 3 except for AOA, which should use data provided by I-load for an AOA.

The tabular I-loaded RTLS data are identified by "use table" parameter names which have a specification of memory configuration 01. The AOA tables have unique I-load parameter names ending with "-E"; and a specification of MC03.

The nominal End-of-Mission tables have unique I-load parameter names ending with "-O" and a specification of MC02.

A suggested implementation of these requirements is illustrated by a detailed flow diagram shown in appendix E under the following name:

4.7 INITIALIZATION OF SPECIFIC OPS 2 NAVIGATION PARAMETERS

It is required that initial values for certain specific parameters be made available for use by the navigation flight software. These parameters can be divided into six categories:

1. Level A Constants - Those parameters with values that are not mission related nor design dependent. These parameters and values are defined in Level A CPDS (SS-P-0002-170D).
2. Mission Dependent Parameters - Those parameters with values that may change from mission to mission. These parameters and their values will be defined in an I-LOAD FSSR that has not been written as of the date of this document.
3. Design Dependent Parameters - Those parameters whose values are considered to be a part of the software design. These parameters and values are defined in this book.
4. Hard Codeable Parameters - Those parameters whose values must be defined but are neither mission dependent nor design dependent and are not defined by the Level A CPDS.
5. Other required initial values - Those parameters whose values do not fit in any of the four above categories.
6. OPS Transition Parameters - Those parameters whose values are needed by the OPS 2 or OPS 8 navigation flight software, or calculated by OPS 2 for an OPS transition to OPS 8, OPS 3, or OPS 00, or calculated by OPS 8 for an OPS transition to OPS 2, OPS 3, or OPS 00.

These six categories of initialization parameters are denoted in the INITIALIZATION CATEGORY column of the variable lists in the appendices by the following abbreviations:

- C - Level A constants
- MD - Mission dependent parameters
- DD - Design dependent parameters
- HC - Hard codeable parameters
- IV - Other required initial values
- OPS - OPS transition parameters

4.8 DOWNLIST REQUIREMENTS

Downlist requirements for the Onorbit/Rendezvous (OPS-2) operations computer load are given in the Computer Program Development Specification (CPDS) Vol 1, Book 4, Downlist/Uplink Software Requirements (SS-P-0002-140F). Data that will be available for downlist may be found in the principal function input/output tables marked with TLM as output destination. They may also be found in the variable lists of appendices A, C, D, E and F indicated by the word "downlist" in the Uplink/Downlist column of the variable lists.

4.9 UPLINK REQUIREMENTS

The following subsections identify uplink requirements to support the orbital operations computer load onboard navigation software. Each subsection identifies a specific set of parameters which are candidates for uplink and details the structure of the formatted load, specifies any OP-CODE checking and/or special processing required as a result of the occurrence of the particular uplinked data, and describes any special constraints involved. All navigation related uplink parameter requirements are grouped into the following categories:

- Orbiter state vector uplink parameters (section 4.9.1)
- Rendezvous vehicle state vector uplink parameters (section 4.9.2)
- Vent/RCS thrust body force vector uplink parameters (section 4.9.3)
- Drag model correction factor uplink parameter (section 4.9.4)
- Covariance matrix uplink parameters (section 4.9.5)
- Landing/TACAN table uplink processing (section 4.9.6)
- Landing site selection parameters (section 4.9.7)

4.9.1 Orbiter State Vector Uplink Parameters (ORBITER_STATE_VECTOR_UPLINK)

The parameters to be candidates for change via command uplink associated with the Orbiter state vector update include the Orbiter M50 position and velocity vectors, and the associated time tag.

A. Detailed Requirements.- The Orbiter M50 position and velocity vectors with the associated time tag (GMT) can be changed via a formatted load structured as described in table 4.9.1-1. The following high-rate special processing is required upon receipt of an Orbiter state vector command uplink load:

1. A bit-string (OP-CODE) shall have been set to the "Orbiter state vector uplink" OP-CODE value (0001001) by the ground uplink processing software when data are received from the ground.
2. The bit-string (OP-CODE) shall first be tested by the special processing software to determine if it equals the value specified for an Orbiter state uplink:

```

|
| OP-CODE = 0001001
|

```

3. If the above is true, a flag (DO_OV_UPLINK) shall be set to ON, and the uplinked Orbiter state vector with associated time tag shall be stored in special locations:

```

DO_OV_UPLINK = ON
R_GND = BUFFER R
V_GND = BUFFER V
T_GND = BUFFER T

```

and the OP-CODE shall be nulled.

OP-CODE = 0000000

Once the special high-rate special processing has been performed by the ground uplink software, additional low-rate special processing is required to be performed at a particular point during execution of the next navigation cycle. Detailed requirements for the low-rate special processing requirements are presented in section 4.2.5.1.

- B. Interface Requirements.- The input/output required for the high-rate special processing s/w are listed in table 4.9.1-2. Required input and output for low-rate special processing s/w are listed in table 4.2.5.1.
- C. Processing Requirements.- The high rate special processing detailed in this section shall be performed at a fast enough rate so that if two command uplinks (Orbiter and target) are transmitted between navigation cycles, both sets of data (including the DO_OV_UPLINK and DO_TV_UPLINK flags) will be

available to the low - (nav) - rate special processing software. The low-rate special processing (section 4.2.5.1) shall be performed during a navigation cycle immediately following the normal state vector propagation and during rendezvous navigation phases covariance matrix propagation subfunctions.

- D. Constraints. - Because of a system software requirement to clear uplink data buffers in a relatively short amount of time, and because of the relatively slow rate at which the onorbit/rendezvous navigation principal function will be operating, a fast-rate special processing function is required to buffer off the data and set flags. There is also a requirement to be able to update both the Orbiter and the target states in a single navigation cycle, if such data has been uplinked.
- E. Supplementary Information. - A suggested implementation of the Orbiter state vector formatted load special processing requirements in the form of detailed flowcharts, are presented in Appendix F under:

ONCRBIT_REND_AUTO_INFLIGHT_UPDATE (low-rate special processing)
CRBITER_STATE_VECTOR_UPLINK (high-rate special processing)

TABLE 4.9.1-2.- ORBITER STATE VECTOR UPLINK INPUT/OUTPUT

Variable Name	Input Source	Output Destination
<u>BUFFER_R</u>	GROUND UPLINK PROCESSOR	
<u>BUFFER_V</u>	GROUND UPLINK PROCESSOR	
<u>BUFFER_T</u>	GROUND UPLINK PROCESSOR	
<u>DO_OV_UPLINK</u>		NAV_ONORBIT_RENDEZVOUS
<u>R_GND</u>		ONORBIT_REND_AUTO_INFLIGHT UPDATE
<u>T_GND</u>		ONORBIT_REND_AUTO_INFLIGHT UPDATE
<u>V_GND</u>		ONORBIT_REND_AUTO_INFLIGHT UPDATE

4.9.2 Rendezvous Vehicle State Vector Uplink Parameters (RENDEZVOUS_STATE-VECTOR_UPLINK)

The parameters to be candidates for change via command uplink associated with the rendezvous vehicle state vector update include the rendezvous vehicle M50 position and velocity vectors, and the associated time tag.

- A. Detailed Requirements.-- The rendezvous vehicle M50 position and velocity vectors can be changed via a formatted load structured as described in table 4.9.2-1. Each load contains a time tag (GMT) associated with the state vector. The following high-rate special processing is required upon receipt of a rendezvous vehicle state vector command uplink load.

1. A bit-string (OP_CODE) shall have been set to the "rendezvous vehicle state vector" OP_CODE value (0001010) by the ground uplink processing software when data are received from the ground.
2. The bit string (OP_CODE) shall first be tested by the special processing software to determine if it equals the value specified for the rendezvous vehicle state uplink,

! OP_CODE = 0001010

3. If the above is true, a flag (DO_TV_UPLINK), shall be set to ON, and the rendezvous vehicle state vector and associated time tag shall be stored in special locations:

DO_TV_UPLINK = ON
 R_TV_GND = BUFFER_RT
 V_TV_GND = BUFFER_VT
 T_TV_GND = BUFFER_TT

and the OP_CODE shall be nulled signifying that the state vector has been transferred to the locations:

OP_CODE = 0000000

Once the above high-rate special processing has been performed by the ground uplink software, additional low-rate special processing is required to be performed at a particular point during execution of the next navigation cycle. This latter class of special processing will actually re-initialize the rendezvous vehicle state vector using the uplinked data. Detailed requirements for this (low-rate) portion of the special processing requirements are presented in section 4.2.5.1.

- B. Interface Requirements.-- The input and output required for the high-rate special processing software are listed in table 4.9.2-2. Input and output for the low-rate special processing software are listed in table 4.2.5.1.

- C. Processing Requirements.-- The high-rate special processing detailed in this section shall be performed at a fast enough rate so that if two command uplinks (Orbiter and/or target) are transmitted between navigation cycles, both data sets (including the DO_OV_UPLINK and DO_TV_UPLINK flags) will be available to the low -(nav)- rate special processing software. The low-rate special processing (section 4.2.5.1) shall be performed during a navigation cycle immediately following normal state vector propagation and, during rendezvous, covariance matrix propagation subfunctions.
- D. Constraints.-- Because of a system software requirement to clear uplink data buffers in a relatively short amount of time, and because of the relatively slow rate at which the onorbit/rendezvous navigation principal function will be operating, a fast-rate special processing function is required to buffer off the data and set flags. There is also a requirement to be able to update both the Orbiter and rendezvous vehicle state vectors on a single navigation cycle if such data have been uplinked.
- E. Supplementary Information.-- A suggested implementation of the formatted rendezvous vehicle state vector load special processing requirements, in the form of detailed flowcharts are presented in Appendix F under:

ONORBIT_REND_AUTO_INFLIGHT_UPDATE (low-rate special processing)
RENDEZVOUS_STATE_VECTOR_UPLINK (high-rate special processing)

TABLE 4.9.2-1- RENDEZVOUS VEHICLE STATE VECTOR UPLINK DATA FORMAT

	BUFFER_VT ₂	Y-Velocity in M50 coord	CW10	SF	ft/sec
	BUFFER_VT ₃	Z-Velocity in M50 coord	CW11	SF	ft/sec
	BUFFER_TT	Time Tag in M50	CW1, CW2	DF	sec

4.9.3 Vent/RCS Body Force Vector Uplink Parameters (VENT_RCS_MODEL_PARAM_UPLINK)

The parameters to be candidates for change via the Vent/RCS thrusting uplink command load include a body contact force VFORCE, to account for venting and uncoupled RCS thrusting and other body contact forces if desired, and the associated action ON/OFF times (TFON and TFOFF). These data are specified by premission I-load values (see section 4.7) or uplinked to be used by the Onorbit/Rendezvous Navigation principal function in both OPS 2 and OPS 8.

ONORBIT_RENDEZVOUS_NAV

A. Detailed Requirements.- The values of the body contact force (VFORCE) and associated on-off times (TFON and TFOFF) may be changed via a formatted command load structured as described in table 4.9.3-1. The following processing will be initiated upon receipt of a Vent/RCS uplink from the ground.

1. A bit-string (OP_CODE) shall have been set to the "Vent/RCS Body Force Vector uplink" OP_CODE value (0101001) by the ground uplink processing software when data are received from the ground.
2. The bit-string (OP_CODE) shall first be tested by the processing software to determine if it equals the value specified for a Vent/RCS uplink:

```

!
! OP_CODE = 0101001
!

```

3. If the above is true, the Vent/RCS Body Contact Force Vector VFORCE and ON/OFF action times (TFON/TFOFF) shall be stored in special locations:

```

VFORCE = BUFFER_B
TFON = BUFFER_O1
TFOFF = BUFFER_O2

```

and the OP_CODE shall be nulled.

```
OP_CODE = 0000000
```

- B. Interface Requirements.- The input and output required for a Vent/RCS uplink are shown in table 4.9.3-2.
- C. Processing Requirements.- The uplink Vent/RCS command load will cause revision of all entries; i.e.,

```

VFORCE
TFON
TFOFF

```

For this reason, all entries of the Vent/RCS command load shall be filled with their desired values (those values desired immediately after the completion of the uplink) even if some of the entries are to remain the same.

D. Constraints.-- None

E. Supplementary Information.-- A suggested implementation of the Vent/RCS body contact force parameter uplink in the form of a detailed flowchart (VENT_RCS_MODEL_PARAM_UPLINK) is presented in Appendix F.

TABLE 4.9.3-1.- VENT/RCS BODY FORCE VECTOR UPLINK DATA FORMAT

4.9.4 Drag Model Correction Factor Uplink Parameters (DRAG_MODEL_PARAM_UPLINK)

The drag model parameter which is a candidate for change via uplink is KFACTOR. Command load uplink capability of this parameter ensures that there exists a means whereby the Orbiter drag coefficient may be adjusted if necessary during an Orbiter propagation mode. The drag model is used by the onorbit/rendezvous navigation principal function during OPS 2 and OPS 8:

ONORBIT_RENDEZVOUS_NAV

- A. Detailed Requirements.- The value of the drag model correction factor (KFACTOR) can be changed via a formatted command load structured as described in table 4.9.4-1. The following processing will be initiated upon receipt of a drag model correction factor uplink from the ground.

1. A bit-string (OP_CODE) shall have been set to the "Drag Model Correction Factor Uplink" OP_CODE (0101010) by the ground uplink processing software when data are received from the ground.
2. The bit-string (OP_CODE) shall first be tested by the processing software to determine if it equals the value specified for a drag model correction factor uplink.

```

! -----
! OP_CODE = 0101010
! -----

```

3. If the above is true, the drag model correction factor (KFACTOR) shall be stored in a special location:

KFACTOR = BUFFER_K

and the OP_CODE shall be nulled.

OP_CODE = 0000000

- B. Interface Requirements.- The input and output required for a drag model correction factor uplink are shown in table 4.9.4-2.
- C. Processing Requirements.- None
- D. Constraints.- None
- E. Supplementary Information.- A suggested implementation of the KFACTOR update capability is presented in Appendix F in the form of a detailed flow-chart, DRAG_MODEL_PARAM_UPLINK.

4.9.5 Covariance Matrix Uplink Parameters (COV_MATRIX_PARAM_UPLINK)

The parameters to be candidates for change via uplink associated with the covariance matrix update include diagonal elements (standard deviations) of the filter state covariance matrix in UVW coordinates and selected correlation coefficients.

A. Detailed Requirements.-- Values of the pre-stored (I-Load) UVW covariance matrix can be changed via a formatted command load structured as described in table 4.9.5-1. Each load will contain data entries to replace the values of the UVW standard deviations (SIG_UPDATE). Detailed descriptions of these parameters can be found in section 4.2.5 and section 4.7. The following processing is required upon receipt of the covariance matrix uplink command load.

1. A bit-string (OP_CODE) shall have been set to the "Covariance Matrix Uplink" OP_CODE (0101011) by the ground uplink processing software when data are received from the ground.
2. The bit-string (OP_CODE) shall first be tested by the processing software to determine if it equals the value specified for a covariance matrix uplink:

! OP_CODE = 0101011

3. If the above is true, the standard deviations (SIG_UPDATE) and correlation coefficients (COV_COR_UPDATE) shall be stored in special locations:

SIG_UPDATE = BUFFER_S

COV_COR_UPDATE = BUFFER_C

and the OP_CODE shall be nulled.

OP_CODE = 0000000

- B. Interface Requirements.-- The input and output required for covariance matrix parameters uplink can be found in table 4.9.5-2.
- C. Processing Requirements.-- Changes to SIG_UPDATE and COV_COR_UPDATE will be made each time the covariance matrix parameters uplink is performed.
- D. Constraints.-- The user shall perform the covariance matrix uplink prior to the state vector uplink when rendezvous navigation is active and it is desired that the uplinked covariance matrix parameters be incorporated along with an uplinked state vector.
- E. Supplementary Information.-- A suggested implementation of the covariance matrix parameters uplink in the form of a detailed flowchart (COV_MATRIX_PARAM_UPLINK) is presented in Appendix F.

4.9.6 Landing/TACAN Site Table Uplink Processing

This subsection provides the software requirements associated with data uplink to the landing site maxi-table, the landing site mini-table, the TACAN site maxi-table, and the TACAN site mini-table.

- A. Detailed Requirements.-- The data set associated with the landing site maxi- and mini-tables and the uplink is as follows.

Geodetic latitude
 Longitude
 Runway azimuth with regard to true north
 Magnetic variation
 Runway altitude above ellipsoid
 MSL altitude above ellipsoid

Runway name identifier (one six character string word in maxi/mini tables- two four character string words required for uplink). In addition, the uplink data set contains a landing site location number which identifies which slot in the landing site maxi-or mini-table is to be changed.

The following special processing is required upon receipt of a landing site uplink as indicated by a flag, DO_LND_SITE_UPLINK, having been set to ON by the ground uplink processing software. The integer, LND_SITE_NO, shall be tested and, if found to lie in the range 1 to 18, the uplink data set (see table 4.9.6-1) shall be loaded into the corresponding slot in the landing site maxi-table. If LND_SITE_NO has a value of 19, 20 or 21, then the uplink data set shall be loaded into the primary, secondary, or alternate table slot, respectively, in the landing site mini-table. Whenever landing site data are loaded into the maxi-or mini-table, the MSBLS availability flag associated with that runway shall be reset to OFF. After the uplinked data have been transferred to the appropriate table slot, the DO_LND_SITE_UPLINK flag shall be reset to OFF.

When LND_SITE_NO lies outside the range 1 to 21, no data transfer shall occur.

The uplink data set associated with the TACAN site maxi- and mini-tables is as follows:

Geodetic latitude
 Longitude
 Magnetic variation
 TACAN altitude above ellipsoid
 MSL altitude above ellipsoid
 TACAN channel/mode identifier
 TACAN bearing bias (not stored in maxi table)
 TACAN range bias (not stored in maxi table)

In addition, the TACAN uplink data set contains a TACAN site location number which identifies which slot in the TACAN site maxi- or mini-table is to be changed.

The following special processing is required upon receipt of a TACAN site table uplink as indicated by a flag, DO_TACAN_SITE_UPLINK, having been set to ON by the ground uplink processing software. The integer, TAC_SITE_NO, shall be tested and, if found to lie in the range 1 to 50, the uplink data set (see table 4.9.6-2) shall be loaded into the corresponding slot in the TACAN site maxi-table. If TAC_SITE_NO lies in the range 51 to 60, the uplink data shall be loaded into the TACAN site mini-table slot corresponding to TAC_SITE_NO minus 50. Finally the DO_TACAN_SITE_UPLINK flag shall be reset to OFF.

If TAC_SITE_NO lies outside the range 1 to 60, no data transfer shall occur.

- B. Interface Requirements.- The input and output requirements for this sub-function are listed in tables 4.9.6-3 and 4.9.6-4, respectively.
- C. Processing Requirements.- To be executed on demand and provided with required input data. If the uplink data words are in units other than radians for angles and feet for lengths, onboard conversion to these units are required before storing into maxi or mini tables.
- D. Constraints.- The task of setting up the uplink buffer data sets and the uplink data availability flags (DO_LND_SITE_UPLINK, DO_TAC_SITE_UPLINK) is assumed to have been performed by some uplink interface software prior to execution of the processing identified in this section. The data availability flags are to be reset to OFF to prevent re-execution of this software.
- E. Supplementary Information.- A suggested implementation, in the form of detailed flowcharts, can be found in Appendix F.

LANDING_SITE_MAXI_MINI_UPLINK

TACAN_SITE_MAXI_MINI_UPLINK

TABLE 4.9.6-1.- LANDING SITE UPLINK DATA FORMAT

Name	Description	Command Word	Data Type	Units	**
LND_SITE_NO	Landing site table slot (1 to 18 - maxi, 19 to 21 - mini)	CW1	I		
RUNWAY_NAME_UL	Runway name identifier	CW2*	C		
SPARE_UL	Runway name identifier- plus fill	CW3*	C	-	
RW_LAT_UL	Runway geodetic latitude	CW4	SF	rad	
RW_LON_UL	Runway longitude	CW5	SF	rad	
RW_AZIMUTH_UL	Runway azimuth measured from true north	CW6	SF	rad	
RW_MAG_VAR_UL	Runway magnetic variation	CW7	SF	rad	
RUNWAY_ALT_UL	Runway altitude above reference ellipsoid	CW8	SF	ft	
RW_DELH_UL	Altitude of mean sea level above ellipsoid at runway	CW9	SF	ft	

*CW2 contains a four character string word.

CW3 contains one additional character, left justified.

These are constructed to form a five string character word for storing (i.e., four characters in CW2 and the left most character in CW3 are combined).

Example:

CW-2	CW-3
EDW1	7bbb
stored	

, where bbb are fill characters which are ignored.

**If the uplinked data words are in units other than those shown, onboard conversion to these units is required before storing into the maxi or mini tables.

TABLE 4.9.6-2.- TACAN SITE UPLINK DATA FORMAT

Uplink Buffer Data		Command	Data	Units
Name	Description	Word	Type	Units
MAGNETIC VARIATION_UL	Magnetic variation at TACAN site	CW1	SF	rad
BIAS_TAC_BRG_UL	TACAN bearing bias*	CW2	SF	rad
BIAS_TAC_R_UL	TACAN range bias*	CW3	SF	ft
TAC_SITE_NO	TACAN site table slot (1 to 50 - maxi, 51 to 60 - mini)	CW4	I	
TACAN_ID_UL	TACAN channel/mode identifier	CW5	I	
LATITUDE_GEODETTIC_UL	TACAN site geodetic latitude	CW6	SF	rad
LONGITUDE_EAST_UL	TACAN site longitude	CW7	SF	rad
ALT_ABOVE_ELLIPSOID_UL	TACAN altitude above reference ellipsoid	CW8	SF	ft
MSL_ABOVE_ELLIPSOID_UL	Altitude of mean sea level above ellipsoid at TACAN site	CW9	SF	ft

* Biases are stored only in mini tables; thus CW-2 and CW-3 are ignored if maxi table is addressed.

** If the uplink data words are in units other than those shown, onboard conversion to these units is required before storing into the maxi or mini tables.

4.9.7 Landing Site Selection Parameters

This subsection provides the requirements associated with the landing site selection uplink which is contained within the Deorbit Guidance PEG-4 and the Deorbit Guidance PEG-7 command uplink loads.

- A. Detailed Requirements. The Deorbit Guidance PEG-4 and PEG-7 command uplinks each contain three integer parameters which represent the maxi table slot locations from which landing site data is to be transferred to the landing site mini table primary, secondary and alternate runway slots. The uplink of these parameters is to cause the activation of the Landing Site Update principal function (see section 4.6) which in turn will accomplish the data transfer. Since the Landing Site Update principal function is designed to also respond to crew inputs via the CRT keyboard, certain special processing is required to provide compatibility with these requirements.

In response to a deorbit guidance uplink, as indicated by the flag, DO_GUID_UPLINK, having been set to ON by the ground uplink processing software, the following is to occur. The uplinked parameters PRI_MAXI_UL, SEC_MAXI_UL, and ALT_MAXI_UL (see tables 4.9.7-1 and 4.9.7-2) are integer values which specify which of the maxi table runways are to be transferred to the respective mini table locations. Each of these parameters is to be tested and the corresponding Landing Site Update input parameters set as follows:

If PRI_MAXI_UL > 0 and PRI_MAXI_UL < 19, then

set ITEM1_IN = ON

PRI_MAXI_SELECT = PRI_MAXI_UL

If SEC_MAXI_UL > 0 and SEC_MAXI_UL < 19, then

set ITEM2_IN = ON

SEC_MAXI_SELECT = SEC_MAXI_UL

If ALT_MAXI_UL > 0 and ALT_MAXI_UL < 19, then

set ITEM3_IN = ON

ALT_MAXI_SELECT = ALT_MAXI_UL

Thus, if it is desired to uplink a deorbit guidance target data set without changing part (or all) of the mini table slots, the respective maxi/mini indicators are uplinked with values outside the 1 to 18 range.

If any of the "ITEM_IN" discrettes has been set to ON by the above processing, the Landing Site Update specialist function software is invoked to accomplish the data transfer. Note that the "ITEM_IN" discrettes are reset to OFF by the Landing Site Update software after completing the data transfer.

Finally the flag DO_GUID_UPLINK is reset to OFF to indicate that the appropriate processing has occurred.

- B. Interface Requirements. The input and output requirements for this subfunction are listed in tables 4.9.7-3 and 4.9.7-4, respectively.
- C. Processing Requirements. To be executed on demand and provided with the required input data.
- D. Constraints. The task of setting up the uplink buffer data sets and the uplink data availability flag is assumed to have been performed by uplink interface software prior to the execution of the processing identified in this section.
- E. Supplemental Information. A suggested implementation, in the form of a detailed flowchart can be found in Appendix E,

4.10 COORDINATE TRANSFORMATIONS

These ten subfunctions provide the capability for transforming parameters specified (or computed) in one coordinate system to another coordinate system. Coordinate system definitions are provided in Appendix C.

Each of the ten subfunctions described in sections 4.10.1 through 4.10.10 may be executed separately. With two exceptions, these subfunctions do not actually perform the coordinate transformation; only the rotation matrix is computed. The two exceptions convert between Earth-fixed coordinates and geodetic parameters.

For consistency, it is assumed that all coordinate systems located on the surface of the Earth are specified in terms of geodetic parameters (i.e., geodetic latitude, longitude, and altitude above the reference ellipsoid) and that all azimuth angles are referenced to true (not magnetic) north.

4.10.1 Transformation From Aries Mean of 1950 to Earth-Fixed

The purpose of this subfunction is to provide a transformation matrix ($M_{M50T0SF_AT_EPOCH}$) from Aries M50 coordinates to Earth-fixed coordinates that account for the rotation, nutation, and precession motion of the Earth at a specified time, T_EPOCH .

This subfunction is not part of the actual onorbit Navigation Software. Its output parameters, $M_{M50T0SF_AT_EPOCH}$ and their corresponding time, T_EPOCH , are to be supplied to the onorbit Navigation Software via I-Load as Mission-Dependent Parameters (see section 4.7 and Appendix C Variable List).

The software will not be designed to preclude any particular value of T_EPOCH , whether future or past except that, if the time desired is in a year other than the one of the mission's commencement, the general time variable is to be continuous over year-end/year-beginning transitions.

4.3.2 Earth-Fixed to M50 (EARTH_FIXED_TO_M50_COORD)

The purpose of this subfunction is to propagate the matrix M_M50TOEF_AT_EPOCH from the last epoch time to the time of interest. This propagation accounts for the Earth's daily rotation effects only. (The nutation and precession computations are lengthy.)

The Earth-fixed coordinate frame of the time of interest is rotated about its Z-axis to obtain the Earth-fixed coordinate frame of the time of the M_M50TOEF_AT_EPOCH matrix. The angle of rotation is the product of the Earth's mean rotational rate relative to the mean of data system and the difference between the matrix's time tag and the time of interest. A matrix that represents this Z-axis rotation is calculated. The matrix that represents the transformation from the Earth-fixed frame of the last epoch time to the mean of 1950 frame is the M_M50TOEF_AT_EPOCH matrix's transpose. Then the desired Earth-fixed to mean of 1950 matrix is the product of the transpose of the M_M50TOEF_AT_EPOCH matrix postmultiplied by the Z-axis rotation matrix.

A. Detailed Requirements. This function is designated in calling routines as

EARTH_FIXED_TO_M50_COORD(TIME)

where TIME -- time of interest measured from the beginning of the particular mission year

EARTH_FIXED_TO_M50_COORD -- Earth fixed to mean of 1950 coordinate transformation matrix of the time of interest

The following steps shall be performed (in the order indicated):

1. The time difference from the epoch time to the current time is calculated:

$$\text{DELT} = \text{TIME} - \text{T_EPOCH}$$

(T_EPOCH is the epoch time).

2. The angle of rotation about the Earth-fixed Z-axis is obtained.

$$\text{LAM} = \text{EARTH_RATE} \text{ DELT}$$

3. The Earth-fixed Z-axis rotation matrix is then defined:

$$M = \begin{pmatrix} \cos(\text{LAM}) & -\sin(\text{LAM}) & 0 \\ \sin(\text{LAM}) & \cos(\text{LAM}) & 0 \\ 0 & 0 & 1 \end{pmatrix} \quad \text{F9}$$

F9 This equation shall be protected against return value of sine or cosine with magnitude greater than unity (Reference 3.6-9).

4. The Earth-fixed to mean of 1950 coordinate transformation matrix is then computed as follows:

$$\text{EARTH_FIXED_TO_M50_COORD} = \text{M_M50TOEF_AT_EPOCH}^T \text{ M}$$

Because of the sparseness of the matrix M, both core and execution time will be conserved by use of the following formulation: For notational convenience, let N denote the matrix M M50TOEF AT EPOCH. The sine and cosine of LAM will be computed once and denoted by CLAM = COS (LAM) and SLAM = SIN (LAM). Then EARTH_FIXED_TO_M50_COORD will be computed as follows:

$$\text{EARTH_FIXED_TO_M50_COORD}_{1,1} = \text{N}_{1,1} \text{ CLAM} + \text{N}_{2,1} \text{ SLAM}$$

$$\text{EARTH_FIXED_TO_M50_COORD}_{1,2} = -\text{N}_{1,1} \text{ SLAM} + \text{N}_{2,1} \text{ CLAM}$$

$$\text{EARTH_FIXED_TO_M50_COORD}_{1,3} = \text{N}_{3,1}$$

$$\text{EARTH_FIXED_TO_M50_COORD}_{2,1} = \text{N}_{1,2} \text{ CLAM} + \text{N}_{2,2} \text{ SLAM}$$

$$\text{EARTH_FIXED_TO_M50_COORD}_{2,2} = -\text{N}_{1,2} \text{ SLAM} + \text{N}_{2,2} \text{ CLAM}$$

$$\text{EARTH_FIXED_TO_M50_COORD}_{2,3} = \text{N}_{3,2}$$

$$\text{EARTH_FIXED_TO_M50_COORD}_{3,1} = \text{N}_{1,3} \text{ CLAM} + \text{N}_{2,3} \text{ SLAM}$$

$$\text{EARTH_FIXED_TO_M50_COORD}_{3,2} = -\text{N}_{1,3} \text{ SLAM} + \text{N}_{2,3} \text{ CLAM}$$

$$\text{EARTH_FIXED_TO_M50_COORD}_{3,3} = \text{N}_{3,3}$$

- B. Interface Requirements. The input and output data are shown in table 4.10.2.
- C. Processing Requirements. This function may be executed as needed. The time (TIME) at which the output transformation matrix (EARTH_FIXED_TO_M50_COORD) is desired must be supplied by the user in elapsed seconds from the beginning of the year of mission commencement.
- A valid M M50TOEF AT EPOCH must be available before this subfunction can be executed.
- D. Constraints. None
- E. Supplementary Information. The Aries mean of 1950 and the Earth-fixed coordinate systems are shown in Appendix C. A suggested implementation in the form of a detailed flowchart may be found in Appendix C under the name:

4.10.3 Geodetic to Earth-Fixed (GEODETC_TO_EF)

This submodule accepts the geodetic parameters of a point and computes the Earth-fixed Cartesian coordinates of that point.

A. Detailed Requirements. This function is addressed in calling modules as

GEODETC_TO_EF(LAT_GEOD,LON,ALT)

This function is referred to internally as

GEODETC_TO_EF(LAT_GEOD,LON,ALT) = R_EF

where	ALT	-- altitude above reference ellipsoid of point of interest
	LAT_GEOD	-- geodetic latitude of point of interest
	LON	-- longitude of point of interest
	<u>R_EF</u>	-- Earth-fixed position vector of point of interest

These equations shall transform the geodetic parameters to Earth-fixed coordinates:

$$R_{EF1} = \left[\frac{EARTH_RADIUS_EQUATOR}{(\cos^2(LAT_GEOD) + (1 - ELLIPT)^2 \sin^2(LAT_GEOD))^{1/2}} + ALT \right] \cdot \cos(LAT_GEOD) \cos(LON) \quad \begin{matrix} F3, \\ F9, F4 \end{matrix}$$

$$R_{EF2} = \left[\frac{EARTH_RADIUS_EQUATOR}{(\cos^2(LAT_GEOD) + (1 - ELLIPT)^2 \sin^2(LAT_GEOD))^{1/2}} + ALT \right] \cdot \cos(LAT_GEOD) \sin(LON) \quad \begin{matrix} F3, \\ F9, F4 \end{matrix}$$

$$R_{EF3} = \left[\frac{(1 - ELLIPT)^2 EARTH_RADIUS_EQUATOR}{(\cos^2(LAT_GEOD) + (1 - ELLIPT)^2 \sin^2(LAT_GEOD))^{1/2}} + ALT \right] \cdot \sin(LAT_GEOD) \quad \begin{matrix} F3, \\ F9, F4 \end{matrix}$$

F3 This equation shall be protected against division by zero (Reference 3.6-3).

F9 This equation shall be protected against return value of sine or cosine with magnitude greater than unity (Reference 3.6-9).

F4 This equation shall be protected against square roots of a negative number (Reference 3.6-4).

- B. Interface Requirements. The input and output data are shown in table 4.10.3.
- C. Processing Requirements. The input angles must be in radians.
- D. Constraints. None
- E. Supplementary Information. The geodetic parameter set and the Earth-fixed coordinate system are illustrated in Appendix C. A suggested implementation in the form of a detailed flowchart may be found in Appendix C under the name:

GEODETIC_TO_EF FUNCTION

4.10.4 Earth-Fixed to Topodetic (EF_TO_TOPDET)

This subfunction accepts the geodetic latitude and longitude of a point in radians and computes the rotation matrix from Earth-fixed coordinates to a topodetic coordinate system for the input location.

Formulation: This subfunction creates the rotation matrix as an Euler Z, Y sequence through the longitude angle (LON) and the geodetic latitude angle plus 90 degrees ($\text{LAT_GEOD} + \pi/2$), respectively.

A. Detailed Requirements. Calling modules address this function as

EF_TO_TOPDET(LAT_GEOD, LON)

This function is referred to internally as

EF_TO_TOPDET(LAT_GEOD, LON) = M

where LAT_GEOD -- geodetic latitude of point of interest
 LON -- longitude of point of interest
 M -- desired Earth-fixed to topodetic coordinate transformation matrix

The transformation matrix shall be calculated as shown here:

$$M = \begin{bmatrix} (-\cos LON \sin LAT_GEOD) & (-\sin LON \sin LAT_GEOD) & (\cos LAT_GEOD) \\ (-\sin LON) & (\cos LON) & 0 \\ (-\cos LON \cos LAT_GEOD) & (-\sin LON \cos LAT_GEOD) & (-\sin LAT_GEOD) \end{bmatrix} \quad F9$$

B. Interface Requirements. The input and output data are shown in table 4.10.4.

C. Processing Requirements. The input variables must be in radians.

D. Constraints. None

E. Supplementary Information. The Earth-fixed and topodetic coordinate systems, and a suggested implementation of this module are provided in Appendix C. A suggested implementation in the form of a detailed flowchart may be found in Appendix C under the name:

EF_TO_TOPDET FUNCTION

F9 This equation shall be protected against return value of sine or cosine with magnitude greater than unity (Reference 3.6-9).

4.10.5 Earth-Fixed to Runway (EF_TO_RUNWAY)

This subfunction accepts the geodetic latitude, longitude, and azimuth of the runway and computes the rotation matrix from the Earth-fixed coordinate system to the runway coordinate system.

Formulation: The Earth-fixed to topodetic subfunction is used to obtain an Earth-fixed to topodetic rotation matrix. Then the Earth-fixed to topodetic matrix is multiplied by an Euler Z rotation matrix through the runway azimuth angle (AZ), measured from true north to the +X-axis of the runway.

A. Detailed Requirements. Other routines designate this function as

EF_TO_RUNWAY(LAT_GEOD,LON,AZ)

in which LAT_GEOD -- runway's geodetic latitude
 LON -- runway's longitude
 AZ -- runway's azimuth
 EF_TO_RUNWAY -- desired Earth-fixed to runway coordinate transformation matrix

The following steps shall be performed (in the order indicated):

1. The Euler Z rotation matrix is calculated.

$$M = \begin{bmatrix} (\cos AZ) & (\sin AZ) & 0 \\ (-\sin AZ) & (\cos AZ) & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad F9$$

2. The Earth-Fixed to Topodetic Function is called and its rotation matrix is premultiplied by the Euler Z rotation matrix to produce the Earth-fixed to runway rotation matrix.

EF_TO_RUNWAY = M EF_TO_TOPDET(LAT_GEOD, LON)

- B. Interface Requirements. The input and output data are shown in table 4.10.5.
- C. Processing Requirements. Input angles must be in radians.
- D. Constraints. None

F9 This equation shall be protected against return value of sine or cosine with magnitude greater than unity (Reference 3.6-9).

- E. Supplementary Information. The Earth-fixed, runway, and topodetic coordinate systems are shown in Appendix C. A suggested implementation in the form of a detailed flowchart may be found in Appendix C under the name:

EF_TO_RUNWAY FUNCTION

TABLE 4.10.5.- EF_TO_RUNWAY FUNCTION INPUT/OUTPUT.- Concluded

Variable Name	Input Source	Output Destination
†	IEF_TO_TOPDET(LAT_GEOD, ILON)	
†		IEF_TO_SCANNER FUNCTION

†Only EF_TO_TOPDET's element values are passed from input source, and only values of EF_TO_RUNWAY's elements are passed to output destination.

4.10.6 Earth-Fixed to Scanner (EF_TO_SCANNER)

The purpose of this subfunction is to compute the rotation matrix from Earth-fixed to scanner coordinates.

Formulation: The Earth-fixed to runway subfunction is executed, with use of the geodetic latitude and longitude of the scanner and the azimuth of the scanner boresight (AZ) from the true north to obtain a rotation matrix.

The rotation matrix is then multiplied by a rotation matrix representing a 180-degree rotation about the X-axis.

A. Detailed Requirements. This function is designated

EF_TO_SCANNER(LAT_GEOD,LON,AZ)

in calling routines.

where	LAT_GEOD	-- geodetic latitude of scanner
	LON	-- longitude of scanner
	AZ	-- azimuth of scanner boresight
	EF_TO_SCANNER	-- desired Earth-fixed to scanner coordinate transformation matrix

This step shall be performed:

The evaluation of the Earth-Fixed to Runway Function is premultiplied by the 180 degree X-axis rotation matrix

$$M = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{pmatrix}$$

to obtain the Earth-fixed to scanner rotation matrix.

EF_TO_SCANNER = M EF_TO_RUNWAY(LAT_GEOD,LON,AZ)

- B. Interface Requirements. The input and output data are given in table 4.10.6.
- C. Processing Requirements. Input angles must be in radians.
- D. Constraints. None

- E. Supplementary Information. The scanner, runway, topodetic, and Earth-fixed coordinate systems are shown in Appendix C. A suggested implementation in the form of a detailed flowchart may be found in Appendix C under the name:

EF_TO_SCANNER FUNCTION

TABLE 4.10.6.- EF_TO_SCANNER FUNCTION INPUT/OUTPUT.- Concluded

Variable Name	Input Source	Output Destination

4.10.7 Transformation From Structural Body to M50 Coordinates (SBODY_TO_M50)

The transformation matrix from structural body to M50 coordinates (MAT) is computed by postmultiplying the transformation matrix from body to M50 coordinates by a matrix representing a 180-degree rotation about the Y-axis.

The transformation from body to M50 coordinates is the transpose of the matrix derived from the quaternion Q_FIFTY_BODY by employing the special purpose matrix function QUAT_TO_MAT.

- A. Detailed Requirements. This subfunction is called with the following internal variables in the IN LIST and the OUT LIST:

IN LIST: Q_FIFTY_BODY

OUT LIST: MAT

where

Q_FIFTY_BODY mean of 1950 to body rotation quaternion

MAT desired structural body to mean of 1950 coordinate transformation matrix

The following steps shall be performed (in the order indicated):

1. The special purpose matrix function QUAT_TO_MAT is called to obtain a mean of 1950 to body rotation matrix.

MATRIX = QUAT_TO_MAT (Q_FIFTY_BODY)

2. Rotate the transpose of the output matrix 180° about the Y-axis.

$$\begin{aligned} \text{MAT}_{1,1} &= -\text{MATRIX}_{1,1} \\ \text{MAT}_{1,2} &= \text{MATRIX}_{2,1} \\ \text{MAT}_{1,3} &= -\text{MATRIX}_{3,1} \\ \text{MAT}_{2,1} &= -\text{MATRIX}_{1,2} \\ \text{MAT}_{2,2} &= \text{MATRIX}_{2,2} \\ \text{MAT}_{2,3} &= -\text{MATRIX}_{3,2} \\ \text{MAT}_{3,1} &= -\text{MATRIX}_{1,3} \\ \text{MAT}_{3,2} &= \text{MATRIX}_{2,3} \\ \text{MAT}_{3,3} &= -\text{MATRIX}_{3,3} \end{aligned}$$

- B. Interface Requirements. Input and output parameters are listed in table 4.10.7.
- C. Processing Requirements. This subfunction may be executed as needed.
- D. Constraints. None

- E. Supplementary Information. A suggested implementation in the form of a detailed flowchart can be found in Appendix C under the name:

SBODY_TO_M50

†Only the values of QUAT_TO_MAT's elements are passed from input source.

4.10.8 Conversion of a Quaternion to a Matrix (QUAT_TO_MAT)

The special purpose matrix function QUAT_TO_MAT computes the transformation matrix, A, associated with a quaternion, Q, as $QUAT_TO_MAT(Q) = A$.

A. Detailed Requirements. Calling modules designate this function

QUAT_TO_MAT(Q)

This function is referred to internally as

$QUAT_TO_MAT(Q) = A$

where Q - quaternion

A - corresponding transformation matrix

The following steps shall be performed (in the order indicated).

$$P2 = Q2 + Q2$$

$$P3 = Q3 + Q3$$

$$P4 = Q4 + Q4$$

$$P5 = P2 Q2$$

$$P6 = P4 Q4$$

$$TEMP = 1.0 - P3 Q3$$

$$A_{1,1} = TEMP - P6$$

$$A_{2,2} = 1.0 - P5 - P6$$

$$A_{3,3} = TEMP - P5$$

$$P5 = P2 Q3$$

$$P6 = P4 Q1$$

$$A_{1,2} = P5 - P6$$

$$A_{2,1} = P5 + P6$$

$$P5 = P2 Q4$$

$$P6 = P3 Q1$$

$$A_{1,3} = P5 + P6$$

$$A_{3,1} = P5 - P6$$

$$P5 = P3 Q_4$$

$$P6 = P2 Q_1$$

$$A_{2,3} = P5 - P6$$

$$A_{3,2} = P5 + P6$$

- B. Interface Requirements. Input and output parameters are listed in table 4.10.8.
- C. Processing Requirements. None
- D. Constraints. None
- E. Supplementary Information. A suggested implementation in the form of a detailed flowchart can be found in Appendix C under the name:

Q	Q_M50BODY_RR	IRR_ANGLE_NAV	
Q	Q_FIFTY_BODY	ISBODY_TO_M50	
A	†		NAV_ONORBIT_RENDEZVOUS, IRR_ANGLE_NAV, ISBODY_TO_M50

†Only values of A's components are passed to output destination.

4.10.9 Earth-Fixed to Geodetic (EF_TO_GEODETTIC)

This function is required to transform a Cartesian position vector in the Earth-fixed (Greenwich) coordinate system to the geodetic parameters: geodetic altitude, longitude, and geodetic latitude.

- A. Detailed Requirements. This subfunction is called with the following internal variables in the IN LIST and the OUT LIST:

IN LIST: R_EF

OUT LIST: LAT_GEOD, LON, ALT

where

R_EF Cartesian position vector

LAT_GEOD geodetic latitude

LON geodetic longitude

ALT geodetic altitude

The following steps shall be performed (in the order indicated):

1. The computation for longitude is:

$$LON = ATAN \left(\frac{R_{EF2}}{R_{EF1}} \right), 0 \leq LON < 2\pi \quad F3, F7$$

2. Computations for geodetic latitude, LAT_GEOD, and height above the reference ellipsoid, ALT, are as follows:

$$R_{XY} = R_{EF1}^2 + R_{EF2}^2$$

$$R = (R_{XY} + R_{EF3}^2)^{1/2} \quad F4$$

$$FLATCON = 1.0 - (1.0 - ELLIPT)^2, \text{ where ELLIPT} = \text{flattening of the reference ellipsoid}$$

F3 This equation shall be protected against division by zero (Reference 3.6-3).

F7 This equation shall be protected against arc tangents with both arguments equal to zero (Reference 3.6-7).

F4 This equation shall be protected against square roots of a negative number (Reference 3.6-4).

79FM10

$$\text{SIN_P} = R_{\text{EF3}}/R$$

F3

$$\text{COS_P} = (R_{\text{XY}})^{1/2}/R$$

F3, F4

$$\text{RAD_P} = \frac{\text{EARTH_RADIUS_EQUATOR}}{\sqrt{1.0 + \text{FLATCON SIN } P^2 / (1.0 - \text{FLATCON})}}$$

F3,
F4

$$\text{DEL} = \frac{\text{FLATCON SIN_P COS_P}}{1.0 - \text{FLATCON COS } P^2}$$

F3

$$\text{DEL_LAT} = \frac{\text{RAD_P DEL}}{R}$$

F3

$$\text{PHI} = \text{ATAN} (\text{SIN_P}/\text{COS_P}), -\pi/2 \leq \text{PHI} \leq \pi/2$$

F3,
F7

$$\text{LAT_GEOD} = \text{PHI} + \text{DEL_LAT} \text{ (in radians)}$$

and

$$\text{ALT} = (R - \text{RAD_P}) (1.0 - 0.50 \text{ DEL DEL_LAT}) \text{ (in feet)}$$

- B. Interface Requirements. The input and output data are shown in table 4.10.9.
- C. Processing Requirements. This subfunction may be executed on demand.
- D. Constraints. None
- E. Supplementary Information. The Earth-fixed coordinate system and geodetic parameters are defined in Appendix C. A suggested implementation in the form of a detailed flowchart may be found in Appendix C under the name:

EF_TO_GEODETTIC

- F3 This equation shall be protected against division by zero (Reference 3.6-3).
- F4 This equation shall be protected against square roots of a negative number (Reference 3.6-4).
- F7 This equation shall be protected against arc tangents with both arguments equal to zero (Reference 3.6-7).

4.10.10 UVW to M50 (UVW_TO_M50)

The purpose of this subfunction is to compute the transformation matrix from UVW coordinates to Aries M50 coordinates, given the position and velocity of the vehicle.

The orientation of the U, V, W system is determined by the Orbiter inertial position and velocity vectors (R, V) at the point (or time) of interest.

A. Detailed Requirements. Users of this function designate it:

UVW_TO_M50(R,V)

where $\begin{matrix} \underline{R} & \text{-- position vector (mean of 1950)} \\ \underline{V} & \text{-- velocity vector (mean of 1950)} \\ \text{UVW_TO_M50} & \text{-- UVW to mean of 1950 coordinate transformation matrix} \end{matrix}$

The following steps shall be performed (in the order indicated):

1. The UVW coordinate frame axes unit vectors in mean of 1950 coordinates are determined. (Z represents the V-axis unit vector to avoid confusion with the velocity vector.)

$$\underline{U} = \underline{R} / |\underline{R}| \quad \text{F3}$$

$$\underline{W} = (\underline{R} \times \underline{V}) / |\underline{R} \times \underline{V}| \quad \text{F3}$$

$$\underline{Z} = \underline{W} \times \underline{U}$$

2. The transformation matrix from UVW coordinates to Aries mean of 1950 is then given by

$$\text{UVW_TO_M50} = \underline{U} | \underline{Z} | \underline{W}$$

B. Interface Requirements. The input and output data are given in table 4.10.10.

C. Processing Requirements. All computations are to be performed in double precision.

D. Constraints. None

E. Supplementary Information. The UVW coordinate system and the Aries M50 system are defined in Appendix C. A suggested implementation in the form of a detailed flowchart may be found in Appendix C under the name:

UVW_TO_M50 FUNCTION

F3 This equation shall be protected against division by zero (Reference 3.6-3).

APPENDIX A

GENERAL REQUIREMENTS FUNCTIONS

CONTENTS

Subject	Page
Variables List	A-7

PRECEDING PAGE BLANK. NOT FILMED

VARIABLES LIST DEFINITIONS

CODE USED FOR VARIABLE DATA TYPE

F: floating point quantity. An n-dimensional floating point vector will be denoted $F(n)$. Similarly, a nxm floating point matrix will be denoted by $F(n,m)$.

I: integer quantity; $I(n)$ will denote an n-dimensional integer vector

B: bit, i.e., data having only values of 0 or 1

C: character; $G(n)$ will denote an n-dimensional character string

CODE USED FOR VARIABLE PRECISION

D: double precision

S: single precision; integer quantities are assumed single precision unless otherwise specified

VARIABLE LOCATION

Compool: Variable value located in common storage, accessible by all functions

Local : Variable is used by one function only, and usable to other functions through call argument only

VARIABLE INITIALIZATION CATEGORY

blank: display is vacant

C: constant (unchanging)

DD: design dependent

HC: hard coded

MD: mission dependent (I-LOAD)

OPS: OPS transition parameter

IV: other required initial values

PRECEDING PAGE BLANK. NOT FILMED

VARIABLE INITIAL VALUE

initial operation sequence computer inputs

VARIABLE UPLINK AND DOWNLIST STATUS

UPLINK: variable is an uplink item

DOWNLIST: variable is a downlist item

UNITS DEFINITIONS

deg: angular measurement, degrees

ft: feet

lb: pounds

n.d.: non-dimensional

rad: radian

sec: time measurement, seconds

slugs: mass measurement, slugs

vary: units have different values which depend on variable use

CDEC1	DF	compool	--	--	--	--	Cosine of solar declination used in ACCEL_ONORBIT density calculations.
C_DENSEA (V96U9094C)	SF	local	DD	295274.7	--	1ft	Constant used in ACCEL_ONORBIT density model.
CDP (V97U6002C)	SF	local	DD	0.78590	--	--	Constant used in ACCEL_ONORBIT drag coefficient calculation.
CDN (V97U5282C)	SF	local	DD	2.41256	--	--	Constant used in ACCEL_ONORBIT drag coefficient calculation.
CDS (V97U6010C)	SF	local	DD	1.92837	--	--	Constant used in ACCEL_ONORBIT drag coefficient calculation.
COAS_ANGLE_BIAS_INIT (V96U9084C-5C)	SF(2)	local	MD	--	--	1rad	Initial value of the COAS angle bias slots in the state vector.
COAS_ANGLES_EDIT_OVERRIDE	B	local	--	--	--	--	Flag used to override (ON) the residual edit test for the COAS angles data.

VARIABLES LIST

Variable name (N/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
COAS_ANGLES_STAT	B	local	--	--	--	--	Flag indicating that COAS angles data are to be processed for statistical display purpose only (ON).
COAS DATA GOOD (V90X4849X)	B	compool	--	--	downlist	--	Snapped COAS flag indicating the use of COAS to track a target. This is used by navigation as a DATA GOOD flag. (STAR TRCK SOP HAL name NAV_SIGHT,N/SID # V95X4779X).
COAS_ENABLE (V93X6225X)	B	compool	--	--	downlist	--	COAS angle ENABLE flag not used in the software but is included here for downlist notification.
COAS_ID (V90J4854C)	I	compool	--	--	downlist	--	Snapped COAS selection flag (STAR TRCK SOP HAL name AXN, N/S ID# V95X4972X).
COAS MARK NUM (V90J4827C)	I	compool	IV	0	downlist	--	COAS measurement mark counter.
CONST	DF	local	--	--	--	sec ³ /ft ²	Temporary variable used in transition matrix computation.
CONT ACC (V90A4944C)	SF	compool	--	--	downlist	ft/sec ²	Contact acceleration (magnitude of the IMU sensed acceleration) used to determine whether IMU data and/or measurement data are to be used.
COS LAG (V96U9086C)	SF	local	DD	0.798 63551	--	--	Cosine of atmospheric bulge lag angle used in ACCEL_ORBIT density model.
COS_PSI	SF	local	--	--	--	--	Variable used in ACCEL_ORBIT atmospheric density model.
COS_SOL_RA	DF	compool	--	--	--	--	Cosine of solar right ascension used in ACCEL_ORBIT density model.
COV ACCEL UVM INIT (V90H4930C-32C)	SF(3)	compool	--	--	--	ft ² /sec ⁴	Vector of unmodeled acceleration bias error variances in UVM coordinates.
COV COR UPDATE (V96H1290C-6C)	SF(7)	compool	MD	--	uplink	--	Vector of correlation coefficients associated with UVM standard deviations (SIG_UPDATE) used for Orbiter/target covariance initialization (ground update).

VARIABLES LIST

Variable name (N/S ID)	Precision & type	Compool or local	Initial-ization category	Initial value	Uplink/downlink	Units	Description
ICW_PWD_FLT (Y901936X)	B	compool	--	--	--	--	Flag indicating (ON) that the IMU use flag has been turned on at least once since the last COW prop.
ICW_PWD_FLT_LAST (Y901845X)	B	compool	--	--	--	--	The last value of COW_PWD_FLT.
ICW_U_A_COAST (Y960995C-7C)	SF(3)	compool	DD	3° 1.8-8	--	ft ² /sec ³	Unmodeled acceleration bias variances for coasting flight.
ICW_U_A_PWD_FLT (Y960996C-100C)	SF(3)	local	DD	13° 36E-2	--	ft ² /sec ³	Unmodeled acceleration bias variances for powered flight.
ICSPST	SF	local	--	--	--	ft	Variable used in ACCEL_ONORBIT atmospheric density model.
ICSSND	SF	local	--	--	--	ft	Variable used in ACCEL_ONORBIT atmospheric density model.
ICURR_ORB_MASS (Y901961C)	SF	compool	--	--	--	slugs	Current Orbiter mass
IC1	DF	local	--	--	--	sec/ft	Scratch variable used in mean conic partials calculations.
IC1	DF	local	--	--	--	--	Auxiliary variable used in F and G series computations and in Pines method.
IC2	SF	local	--	--	--	sec ² /ft ²	Scratch variable used in mean conic partials calculations.
IC2	DF	local	--	--	--	--	Auxiliary variable used in F and G series computations and in Pines method.
ID	SF(3)	local	--	--	--	ft/sec ²	Variable used in ACCEL_ONORBIT to define vehicle drag acceleration.
IDA_THRESHOLD (Y901877C)	SF	local	--	--	--	micro G's	Threshold value for magnitude of sensed acceleration.
IDA_THRESHOLD_TEST	SF	local	--	--	--	ft/sec ²	Threshold test value for magnitude of sensed acceleration.
IDEG_PER_RAD	SF	compool	C	--	--	deg/rad	Conversion factor from radians to degrees.

VARIABLES LIST

Variable name (N/S ID)	Precision & type	Compool or local	Initialization category	Initial value	Uplink/downlink	Units	Description
DELQ	DF	compool	--	--	--	lvary	Measurement residuals.
DELTA_RESID_RATIO (V96U3107C)	SF	local	ID	.2	--	--	Increment on the residual edit test ratio when data is forced.
DELTA_T	DF	local	--	--	--	lsec	Time interval between two positions in a conic (P and G series).
DELTA_T_COAS	SF	local	--	--	--	lsec	Time since last COAS measurement processing.
DELTA_T_COAS_MAX (V96U9108C)	SF	local	ID	120.	--	lsec	Maximum age of COAS measurement before navigation will not process it.
DELTA_T_COAS_MIN (V96U9109C)	SF	local	ID	1.	--	lsec	Minimum change in COAS time tag before it is considered by navigation to be a new measurement.
DELTA_T_CO	SF	compool	--	--	--	lsec	Time interval between two positions in a conic.
DELTA_T_ST	SF	local	--	--	--	lsec	Time difference between current star tracker measurement time and last star tracker measurement time.
DELTA_T_ST_MIN (V96U7106C)	SF	local	ID	1.	--	lsec	Minimum change in star tracker time tag needed to verify that the star tracker data has changed.
DELTA_T_M	SF	local	--	--	--	lsec	Time interval for the mean conic partial transition matrix calculation.
D_PIN	DF	local	--	--	--	--	Temporary storage variable used in Pinose formulation (call argument to P and G).
D_PIN_TEMP	DF	compool	HC	0.	--	ft ² /sec	Temporary storage for D_PIN (Pinose method).
DPL	B	compool	HC	1	--	--	Flag indicating activation (1) or deactivation of drag model.
DIAG	DF	local	--	--	--	lsec	Scratch variable.

VARIABLES LIST

Variable name (N/S ID)	Precision & type	Compool or local	Initialization category	Initial value	Uplink/downlink	Units	Description
IDID COVAR REINIT (V9011515X)	B	compool	IV	OFF	downlink	--	Positive feedback flag indicating (ON) that a covariance reinitialization has been performed.
IDID ONS TO TOT (V9021513X)	B	compool	IV	OFF	downlink	--	Positive feedback flag indicating (ON) that a state vector transfer has been performed (TOT = ONS).
IDID TOT TO ONS (V9021514X)	B	compool	IV	OFF	downlink	--	Positive feedback flag indicating (ON) that a state vector transfer has been performed (ONS = TOT).
ID_IN	DF	local	--	--	--	ft ² /sec	Dot product of position and velocity used in Pines method in call to P and G series.
IDISP DELQ (V90H0212C, 14C, 21C, V90A0711C)	SP(4)	compool	--	--	downlink	lvary	Display measurement residual.
IDISP EDIT (V90X0213X, 15X, 21X, 0712X)	C(4)	compool	IV	"blank"	downlink	--	Display edit status indicator.
IDISP 31G (V90H0216C, 17C, 22C, 713C)	SP(4)	compool	--	--	downlink	--	Display residual edit ratio.
IDN	B	local	IV	OFF	--	--	Flag indicating use of or nonuse of drag model in ACCEL_GUMMERT.
ID_NW_AH	DF	local	--	--	--	rad	Difference in mean anomalies used to solve Kepler's equations, used in P and G series.
IDP (V9023963X)	B	compool	--	--	--	--	Flag indicating use or nonuse of drag acceleration in prediction.
IDUN	DF	local	--	--	--	--	Local variable used in ACCEL_GUMMERT gravitational acceleration computation.
ID COAS ANGLES NEW (V9014800X)	B	local	--	--	downlink	--	On-off switch indicating (ON) that COAS angles data have been selected for processing.

VARIABLES LIST

Variable name (M/3 ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
IDO_COAS_ANGLES_NAV_ LAST (V90X4725X)	B	compool	--	--	--	--	On-off switch indicating (ON) that COAS angles data were selected for processing in the last filter cycle.
IDO_COVAR_REINIT (V93X6233X)	B	compool	--	--	--	--	Flag indicating (ON) the performance of covariance matrix reinitialization.
IDO_FLTR_SLOW_RATE (V93X6235X)	B	compool	IV	ON	--	--	Flag indicating rendezvous filter rate: ON = slow rate OFF = fast rate
IDOING_FLTR_SLOW_RATE (V90X1365X)	B	compool	IV	ON	downlist	--	Flag indicating (ON) rendezvous filter rate is slow, and (OFF) rendezvous filter rate is fast. Provides positive feedback to REL_NAV DISPLAY.
IDOING_MEAS_ENABLE (V90X1417X)	B	compool	IV	OFF	downlist	--	Flag indicating (ON) measurement data are being processed and (OFF) measurement data are not being processed. Provides positive feedback to REL_NAV DISPLAY.
IDOING_PWRD_FLT_NAV (V90X1289X)	B	compool	IV	OFF	downlist	--	Flag indicating (ON) that a powered flight navigation phase is currently active and (OFF) a nonpowered flight nav phase is active. Provides positive feedback to REL_NAV DISPLAY.
IDOING_REND_NAV (V90X4765X)	B	compool	IV	OFF	downlist	--	Flag indicating (ON) a rendezvous navigation phase is active and (OFF) a non-rendezvous navigation phase is active. Provides positive feedback to REL_NAV DISPLAY.
ID_ONE	DF	local	--	--	--	ft ² /sec	Dot product of position and velocity vectors for transition matrix computation and P and G series.
IDO_ORB_TO_TGT (V93X6215X)	B	compool	--	--	--	--	Flag indicating (ON) state vector transfer (TGT = ORB).

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
IDO_OV UPLINK (V90X4754X)	B	compool	IV	OFF	--	--	Flag indicating (ON) that data have been uplinked for Orbiter state vector update.
IDO_RR ANGLES NAV (V90X4866X)	B	local	--	--	downlist	--	Flag indicating (ON) that rendezvous radar angles data have been selected for processing.
IDO_RR ANGLES NAV_LAST (V90X4726X)	B	compool	--	--	--	--	Flag indicating (ON) that rendezvous radar angles data were selected for processing in the last filter cycle.
IDO_RDOT NAV_LAST (V90X4727X)	B	compool	--	--	--	--	Flag indicating (ON) that rendezvous radar range and range rate data were selected for processing in the last filter cycle.
IDO_ST ANGLES NAV (V90X4868X)	B	compool	--	--	downlist	--	Switch indicating (ON) that star tracker angles data have been selected for processing.
IDO_ST ANGLES NAV_LAST (V90X4728X)	B	compool	--	--	--	--	Flag indicating (ON) that star tracker angles data were selected for processing in the last filter cycle.
IDO_TGT TO ORB (V93X6216X)	B	compool	--	--	--	--	Flag indicating (ON) state vector transfer (ORB = TGT).
IDO_TV UPLINK (V90X4757X)	B	compool	IV	OFF	--	--	Flag indicating (ON) that data have been uplinked for target state vector update.
ID_SS (V90V4842C-44C)	SF(3)	compool	--	--	downlist	ft/sec ²	Drag of Shuttle for downlist.
IDT_COV (V90W1366C)	DF	compool	--	--	downlist	sec	Change in time since the last COV propagation.
IDT_FILT (V90W4946C)	DF	compool	--	--	--	sec	Interval over which to propagate the state vector.

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
DT_NAV_STATE_PROP (V95U8683C)	SF	compool	DD	4	--	sec	Onorbit/rendezvous nav state vector propagation rate.
DT_STEP	DF	local	--	--	--	sec	Integration step size for prediction or propagation.
ID_TWO	DF	local	--	--	--	ft ² /sec	Dot product of the position and velocity vectors for the transition matrix computation and P and Q series.
DW_COV (V90L4772C, 891C, 892C)	SF(3)	compool	--	--	downlist	ft/sec	Change in velocity since the last COV propagation.
DW_FILT (V90L4953C -55C)	SF(3)	compool	--	--	--	ft/sec	Differences between accumulated sensed IMU readings on the present cycle and the previous cycle (M50).
DW_IN	SF(3)	local	--	--	--	ft/sec	Input change in velocity used in SUPER_G integrator.
IE (V90U4006C -09C V90U4011C -19C V90U4026C -38C V90U4045C -57C V90U4064C -76C V90U4083C -95C V90U4103C -15C V90U4122C -34C V90U4141C -53C V90U4160C -72C V90U4179C -91C V90U4198C -200C V90U4202C -11C V90U4218C -30C V90U4237C -49C)	IDF(13,13)	compool	--	--	downlist	vary	Filter covariance matrix.
EARTH_MU	DF	compool	C	--	--	ft ³ /sec ²	Gravitational constant of the Earth.

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
EARTH_POLE	DF(3)	compool	C	--	--	--	Unit vector in direction of Earth's axis of rotation.
EARTH_RADIUS_EQUATOR	DF	compool	C	--	--	ft	Earth's equatorial radius.
EARTH_RADIUS_GRAV	DF	local	C	--	--	ft	Earth's radius used for gravitational accelerations in ACCEL_ONORBIT.
EARTH_RATE	DF	compool	C	--	--	rad/sec	Earth's angular rotation rate.
EB_COPY	DF(13)	local	--	--	--	vary	Covariance matrix times the partials vector.
EDIT_FLAG	C	compool	--	--	--	--	Five valued flag used to indicate the status of the sensor measurement processing: OFF - not suitable for processing ON - edited by the residual edit test STAT - processed for statistical display only PROCESSED - processed normally FORCED - processed through force command
ELLIPT	DF	compool	C	--	--	--	Earth's ellipticity constant.
EPS_TIME (V96U9115C)	SF	local	DD	.01	--	sec	Minimum time separation for state vector interpolation.
ERR	DF	local	--	--	--	rad	Auxiliary variable used in P and G series (conic solution) calculations.
EVENT E1 (V90X8164X)	B	compool	IV	OFF	downlist	--	OPS 3 to MM201
EVENT 60 (V90X8189X)	B	compool	IV	OFF	downlist	--	MM106 to MM201

VARIABLES LIST

Variable name (N/S ID)	Presi- sion & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlink	Units	Description
EVENT 60A (V9018160X)	B	compool	IV	OFF	downlink	--	OPS 8 to M201
EVENT 60B (V9018645X)	B	compool	IV	OFF	downlink	--	M201 to OPS 8
EVENT 60H (V9018644X)	B	compool	IV	OFF	downlink	--	OPS 8 to OPS 3
EVENT 67 (V9018646X)	B	compool	IV	OFF	downlink	--	M201 to M202
EVENT 73 (V9018200X)	B	compool	IV	OFF	downlink	--	M202 to M201
EVENT 82 (V9018655X)	B	compool	IV	OFF	downlink	--	M201 to OPS 00
EVENT 84 (V9018148X)	B	compool	IV	OFF	downlink	--	OPS 00 to M201
EVENT 85 (V9018180X)	B	compool	IV	OFF	downlink	--	M201 to OPS 3
EXP SHAPE FACTOR (V9705334C)	SF	local	ID	0.65793	--	--	Constant used in drag model drag coefficient calculation.
F2	DF	local	--	--	--	--	Closed form version of the F time series.
F201	DF	local	--	--	--	sec ⁻¹	Closed form version of the time derivative of F series.
FIFTY	DF(3,3)	local	--	--	--	--	Transformation matrix Earth fixed to N50 used in ACCEL_
							ORIGIN.

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
FILT UPDATE (V90X0224X)	B	compool	IV	OFF	--	--	Flag indicating (ON) that current navigation cycle is complete.
IFM1	DF	local	--	--	--	--	Auxiliary variable for F minus 1.
IF1 IF2 IF3 IF4	DF	local	--	--	--	--	Auxiliary variables in gravitational acceleration calculations used in ACCEL_ONORBIT.
IG	DF	local	--	--	--	sec	Closed form version of the G time series.
IG	DF(3)	local	--	--	--	ft/sec ²	Gravitational acceleration in ACCEL_ONORBIT.
IG_CENTRAL	DF(3)	compool	--	--	--	ft/sec ²	Gravitational acceleration due to Earth as a point mass.
IGDI	SF	local	--	--	--	--	Atmospheric density diurnal coefficient used in ACCEL_ONORBIT.
IGDIE (V96U9116C)	SF	local	DD	1.375	--	--	Exponent of atmospheric density diurnal coefficient used in ACCEL_ONORBIT.
IGDM1	DF	local	--	--	--	--	Auxiliary variable for GDOT minus 1.
IGDOT	DF	local	--	--	--	--	Closed form version of the time derivative of the G series.
IG_INT	DF(3)	local	--	--	--	ft/sec ²	Intermediate value of acceleration used in SUPER-G integration.
IGHD	I	local	--	--	--	--	Flag indicating degree of gravitational potential model in ACCEL_ONORBIT.
IGH_DEG (V96U9117C)	I	compool	DD	4	--	--	Flag indicating the degree of gravitational potential model.

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
!GM_DEG_LOW (V96U9118C)	I	compool	DD	2	--	--	Lowest degree of potential model in calls to the acceleration function; used for sensed velocity, powered flight integration.
!GM_DP (V94J3975C)	I	compool	--	--	--	--	Flag indicating the degree of gravitational potential model for prediction.
!GMO	I	local	--	--	--	--	Flag indicating order of gravitational potential model to be used in ACCEL_ONORBIT.
!GM_DP (V94J3963C)	I	compool	--	--	--	--	Flag indicating the order of the gravitational potential model to be used for prediction.
!GM_ORD (V96U9119C)	I	compool	DD	2	--	--	Flag indicating the order of the gravitational potential model.
!GM_ORD_LOW (V96U9120C)	I	compool	DD	0	--	--	Lowest order of potential model in calls to the acceleration function; used for sensed velocity powered flight integration.
!G_NEW (V90U4940C-42C)	DF(3)	compool	--	--	downlist	!ft/sec ²	Orbiter acceleration vector (M50).
!GO	SP	compool	C	--	--	!ft/sec ² / !g	Earth gravity acceleration constant.
!G_ONE	DF(3)	local	--	--	--	!ft/sec ²	Acceleration vector in transition matrix calculation.
!G_OUT	DF(3)	local	--	--	--	!ft/sec ²	Acceleration vector used in SUPER_G.
!G_TV (V90L4961C-63C)	DF(3)	compool	--	--	downlist	!ft/sec ²	Target vehicle acceleration vector (M50).

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
IG_TV_LAST (V90A4796C,97C,88C)	DF(3)	compool	--	--	--	ft/sec ²	Target vehicle acceleration vector, last value (M50).
IG_TWO	DF(3)	local	--	--	--	ft/sec ²	Acceleration vector in transition matrix calculation.
IG_2_FPS2	SF	compool	C	--	--	lb/slugs	Mass to weight conversion.
IHORIZ	SF	local	--	--	--	rad	Filter estimate of the horizontal angle measurement.
II	I	local	--	--	--	--	Counter
IATM	I	local	--	--	--	--	Attitude mode flag that controls the use or nonuse of prestored average area, mass, and drag coefficient of Orbiter or target vehicle.
II_CYCLE (V90J4889C)	I	compool	--	--	downlist	--	Counter for the navigation cycle.
IDM	B	local	--	--	--	--	Flag indicating the activation (1) or deactivation (0) of the drag model.
ID_MATRIX_3X3	SF(3,3)	local	HC	$\begin{bmatrix} 1. & 0. & 0. \\ 0. & 1. & 0. \\ 0. & 0. & 1. \end{bmatrix}$	--	--	3 by 3 identity matrix.
IDRAG (V90X4950X)	B	compool	--	--	--	--	Drag model flag used by state prop.
IGD (V90J4947C)	I	compool	--	--	--	--	Temporary storage for the potential model degree used by state prop.
IGO (V90J4948C)	I	compool	--	--	--	--	Temporary storage for the potential model order used by state prop.

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
I_N	SF(3)	local	--	--	--	--	Raw vector of M50 to sensor transformation matrix used in angles partials calculation.
I_RHD	SF(3)	compool	--	--	--	ft	Unit line-of-sight vector.
IMU_NAV_ACCEL_THRESH (V93A6710C)	SF	compool	MD	--	downlist	micro-g's	Crew selected acceleration threshold value for incorporating IMU data into nav.
IVENT (V90X4951X)	B	compool	--	--	--	--	Temporary value of venting model flag used in state propagator.
IWM	B	local	--	--	--	--	Flag indicating activation (1) or deactivation (0) of the venting and RCS uncoupled thrusting model.
IJ	I	local	--	--	--	--	Counter.
IK	I	local	--	--	--	--	Counter.
KFACTOR (V96U8173C)	SF	compool	MD	--	uplink	--	Drag model correction factor used in ACCEL_ONORBIT drag model.
K_RESID_EDIT (V96U9121C)	SF	local	DD	225.	--	--	Residual edit test scale factor.
K_UND_WGT (V97U5350C)	SF	local	DD	0.2	--	--	Filter underweighing factor.
IL	I	local	--	--	--	--	Counter.
ILOC (V96U9122C)	DF	local	MD	--	--	--	Coefficient used in ACCEL_ONORBIT solar ephemeris model.
ILOS	DF	local	--	--	--	rad	Longitude of the Sun in M50 coordinates.

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
!COSK1 (V96U9123C)	DF	local	MD	--	--	--	Coefficient used in ACCEL_ONORBIT solar ephemeris model.
!COSK3 (V96U9124C)	DF	local	MD	--	--	--	Coefficient used in ACCEL_ONORBIT solar ephemeris model.
!LOS_R (V96U9125C)	DF	local	DD	1.9909865 94E-7	--	rad/sec	Coefficient used in ACCEL_ONORBIT solar ephemeris model.
!LOS_ZERO (V96U9126C)	DF	local	MD	--	--	rad	Coefficient used in ACCEL_ONORBIT solar ephemeris model.
!MANUAL_EDIT_OVERRIDE	B	compool	--	--	--	--	Copy of the manual edit override flag of sensor data type currently being processed that is sent to the filter.
!MASS_INIT (V90U4938C)	SF	compool	OPS	--	--	slugs	Used for OPS 2, 8, 0 initialization of current Orbiter mass.
!MAT	SF(3,3)	local	--	--	--	--	UVW to M50 transformation matrix for the filtered vehicle in COV prop.
!MAX TIME TOL (V96U8685C)	SF	local	DD	54000.	--	!sec	Maximum time threshold for the state vector prediction task. If the absolute value of the difference between current filter time and the state vector exceeds this threshold, no state vector prediction will take place.
!M_BODYM50	SF(3,3)	compool	--	--	--	--	Body to M50 transformation matrix.

VARIABLES LIST

Variable name (N/S ID)	Precision & type	Compool or local	Initialization category	Initial value	Uplink/downlink	Units	Description
IN_BODY_TO_COAS (V9609127C-44C)	SF(3,3,2)	local	ID	$\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$	--	--	Body to COAS coordinates transformation matrix.
IN_BODY_TO_BR (V9309185C-53C)	SF(3,3)	compool	ID	$\begin{bmatrix} 0 & 0 & -1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{bmatrix}$	--	--	Body to BR coordinates transformation matrix.
IN_EAS_ENABLE (V9316232X)	B	compool	IV	OFF	--	--	Flag indicating that measurement processing is enabled during IN202.
IN_EAS_STAT	B	local	--	--	--	--	Temporary flag used in measurement selection.
IN_EAS_THRESHOLD (V9609154C)	SP	compool	ID	10.00016	--	ft/sec ²	Threshold value for the magnitude of sensed accelerations for nonuse of measurement data.
IN_N_202 (V9018656X)	B	compool	--	--	--	--	Major mode 202 indicator.
IN_N50_TO_BODY_COAS (V9004857C-45C)	SF(3,3)	compool	--	--	downlink	--	Snapped variable for the N50 to body coordinates transformation matrix at the time of COAS data snap (STAR TRACK SGP HAL name T_N50_BODY, N/S ID #V9304809-17C).
IN_N50_TO_SENSOR	SF(3,3)	compool	--	--	--	--	N50 to sensor coordinates transformation matrix for the sensor type being processed.
IN_N50_TO_ST (V9004920C-28C)	SF(3,3)	compool	--	--	downlink	--	Snapped variable for N50 to star tracker coordinate transformation matrix (STAR TRACK SGP HAL name T_N50_ST, N/S ID #V9304800-48C).

VARIABLES LIST

Variable name (N/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlink	Units	Description
MS_SELQ	DF	local	--	--	--	l-vary	Estimated variance of the computed sensor measurement.
MS_POS_UMB_WGT (V9014251C)	SF	local	DD	5.0E 4	--	ft ²	Threshold of the Shuttle position variances for filter underweighting.
IN_UWV_MSO	DF(3,3)	compool	--	--	--	--	UWV to MSO transformation matrix.
IN	I	local	--	--	--	--	Counter.
IN_ACCEPT	I(A)	compool	IV	0	downlink	--	Counter for the number of data marks that have been used to update the navigation state vector.
INV_ANGLELES_AIP (V9014253C)	C	compool	--	--	downlink	--	Auto/Inhibit/Force switch used in nav for the currently enabled angles data set.
INV_CURR_OSB_HABS (V9004254C)	SF	compool	--	--	downlink	ls-lugs	Current Orbiter mass used in nav.
INAV_DO_CVAR_REINIT (V9014256X)	B	compool	--	--	downlink	--	Nav flag tested to determine when to reinitialize the covariance matrix.
INAV_DO_FLTR_SLOW_RATE (V9014257X)	B	compool	--	--	downlink	--	Nav flag indicating rendezvous filter rate: ON = slow rate OFF = fast rate
INAV_DO_OSB_TO_TOT (V9014258X)	B	compool	--	--	downlink	--	Nav flag indicating (ON) crew - requested state vector transfer (Orbiter to target).
INAV_DO_OV_UPLINK (V9014260Z)	B	compool	--	--	downlink	--	Nav flag indicating (ON) Orbiter state vector uplink has occurred.
INAV_EC_TOT_TO_OSB (V9014259X)	B	compool	--	--	downlink	--	Nav flag indicating (ON) a crew requested state vector transfer (target to Orbiter).

VARIABLES LIST

Variable name (N/S ID)	Precision & type	Compool or local	Initialization category	Initial value	Uplink/downlink	Units	Description
NAV NO TV UPLINK (V90J4261X)	B	compool	--	--	downlink		Nav flag indicating (ON) target state vector/uplink has occurred.
NAV MEAS (V90J4267X)	B	compool	IV	OFF	downlink	--	Flag indicating (ON) that sensor measurements are to be processed.
NAV MEAS ENABLE (V90J4262X)	B	compool	--	--	downlink	--	Nav flag indicating (ON) that measurement processing is enabled in MW 202.
NAV MW 202 (V90J4263X)	B	compool	--	--	downlink	--	Major mode 202 indicator for NAV.
NAV PWED FLT NAV (V90J4264X)	d	compool	--	--	downlink	--	Flag indicating (ON) to NAV that powered flight navigation should be exercised.
NAV RANGE AIP (V90J4266C)	C	compool	--	--	downlink	--	Auto/Inhibit/Force switch used in NAV in processing the rendezvous radar range measurements.
NAV ROOT AIP (V90J4269C)	C	compool	--	--	downlink	--	Auto/Inhibit/Force switch used in NAV in processing the rendezvous radar range rate measurements.
NAV RN AREAS ENABLE (V90J4273X)	B	compool	--	--	downlink	--	Rendezvous radar angles enable flag for NAV.
NAV_SIG (V90J4274X)	SF(n)	compool	--	--	--	--	Copy of the residual edit test ratios for the sensor measurements processed.
NAV ST ENABLE (V90J4278X)	B	compool	--	--	downlink	--	Star tracker angles enable flag for NAV.
IN_CYCLE (V90J4273C)	I	compool	--	--	--	--	Frequency at which measurements are to be processed and the covariance matrix propagated.

VARIABLES LIST

Variable name (N/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlink	Units	Description
IN_CYCLE_SLOW (V960662C)	I	compool	DD	4	-	---	Multiplier for frequency of covariance matrix propagation.
IN_CYCLE_FAST (V960661C)	I	compool	DD	2	-	---	Multiplier for frequency of covariance matrix propagation.
INOLSY NAV MEAS (V9014537X)	B	-	IV	OFF	-	---	Flag indicating (ON) that the sensed acceleration is above MEAS_THRESHOLD and measurement data are not to be used.
IN_REJECT (V901407C,06C,05C, 06C)	I(4)	compool	IV	0	downlink	---	Counter for the number of data marks that have been edited by the navigation filter.
IN_STEPS	I	local	-	-	-	---	Number of integration steps in the prediction or propagation interval.
INUM KEP_ITER	I	local	HC	5	-	---	Maximum number of iterations in the solution of Kepler's equation (P and Q).
IN1	I	local	-	-	-	---	Variable used in ACCEL_UNCORRIT Earth gravitational coe.
IONEG_C (V9609157C)	DF	local	DD	11.990968 7152-7	-	rev/sec	Coefficient used in ACCEL_UNCORRIT solar spherics model.
IONEGA	DF(13)	local	-	-	-	revary	Kalman gains vector.
IONEGRIH	DF	local	-	-	-	---	Auxiliary variable used in solving Kepler's equation (P and Q series).
IOFS_2_OR_8_INITIALIZE COMPLETE (V9011242X)	B	compool	-	-	-	---	Signal to HSC indicating that initialization of user parameter state propagation quantities is complete.

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
IOV_PREDICT_FAIL (V90X4770X)	B	compool	--	--	downlist	--	Flag which indicates that the time threshold, MAX_TIME_TOL, has been exceeded and consequently no Orbiter state vector prediction will take place.
IPHASE_C (V9609158C)	DF	local	MD	--	--	rad	Coefficient used in ACCEL_ONORBIT polar ephemeris model.
IPHI	DF(6,9)	local	IV	0.	--	vary	State transition matrix from previous filter time to current time.
IPHI_BIAS	DF(4)	local	--	--	--	--	Diagonal elements of the sensor bias portion of the state transition matrix.
IPHI_MC	DF(6,6)	local	--	--	--	vary	Patch transition matrix computed by mean conic partials.
IPHI_PATCH	DF(6,6)	compool	--	--	--	vary	Transition matrix for converting from time of measurement to current time.
IPHI_UNMOD_ACC	DF	local	--	--	--	--	Diagonal elements of the unmodeled acceleration portion of the state transition matrix.
PI	DF	local	C	--	--	--	Transcendental constant which is the ratio of the circumference of a circle to its diameter.
IPREC_STEP_PRED (V9808726C)	SF	compool	DD	300.0	--	sec	Integration step size for precise prediction.
IPRED_ORB_AREA (V9306955C)	SF	compool	--	--	downlist	ft ²	Orbiter's cross-sectional area for use in prediction.
IPRED_ORB_CD (V9306954C)	SF	compool	--	--	downlist	--	Orbiter's drag coefficient for use in prediction.

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
IPRED ORB MASS (V93U6953C)	SF	compool	--	--	downlist	slugs	Orbiter mass used in prediction.
IPRED STEP (V94W3964C)	SF	compool	--	--	downlist	sec	Prediction step size.
IPRED STEP OPS INIT (V96U8686C)	DF	local	DD	610.	--	sec	Initial predictor step size used in OPS_2_CR_8_INITIALIZE.
IPRED_TASK_COMPLETE	B	local	--	--	--	--	A flag, local to the state vector prediction task, indicating that the prediction task is complete.
IPRED USE (V90J4768CA)	I	compool	IV	0	downlist	--	A flag, having values 0 thru 9, which indicates to the user of the state vector prediction task the status of the prediction task.
IPWRD FLT NAV (V93X5408X)	B	compool	--	--	downlist	--	Flag indicating use of powered flight propagation (ON) or coasting flight propagation (OFF).
IQ_COAS_HORIZ (V90U4847C)	SF	compool	--	--	downlist	rad	Snapped variable for the COAS horizontal angle measurement (STAR TRCK SOP HAL name COAS_HORIZ, M/S ID #V95U4969C).
IQ_COAS_VERT (V90U4848C)	SF	compool	--	--	downlist	rad	Snapped variable for the COAS vertical angle measurement (STAR TRCK SOP HAL name COAS_VERT, M/S ID #V95U4992C).
IQ_HORIZ	SF	local	--	--	--	rad	Measurement from horizontal measurement sensor.
IQ_M50BODY_IMU (V95U0873C -6C)	SF(4)	compool	--	--	downlist	--	Snapped variable for the Shuttle attitude quaternion at the time of the IMU data snap (JRB ATT PROC HAL name Q_BOD_M50, M/S ID# V90U2240-3C).
IQ_M50BODY_RR (V90U4829C -32C)	SF(4)	compool	--	--	downlist	--	Snapped Shuttle attitude quaternion at the time of the rendezvous radar data snap (RR SOP HAL name Q_M50BODY_RR, M/S ID# V95U4312-15C).

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
IQ_RR_RNG (V90U4895C)	SF	compool	--	--	downlist	ft	Snapped variable for the rendezvous radar range measurement (RR SOP HAL name RR_RANGE0, M/S ID# V95H4287C).
IQ_RR_RNG_DOT (V90U4896C)	SF	compool	--	--	downlist	ft/sec	Snapped variable for the rendezvous radar range rate measurement (RR SOP HAL name RR_RNGRO, M/S ID# V95H4288C).
IQ_RR_SHFT (V90U4893C)	SF	compool	--	--	downlist	deg	Snapped variable for the rendezvous radar shaft angle measurement (RR SOP HAL name RR_ROLLO, M/S ID # V95H4284C).
IQ_RR_TRUN (V90U4894C)	SF	compool	--	--	downlist	deg	Snapped variable for the rendezvous radar trunnion angle measurement (RR SOP HAL name RR_PITCH0, M/S ID # V95H4281C).
IQ_ST_HORIZ (V90U4833C)	SF	compool	--	--	downlist	rad	Snapped variable for the star tracker horizontal angle measurement (STAR TRCK SOP HAL name H_NAV, M/S ID # V95H4753C).
IQ_ST_VERT (V90U4834C)	SF	compool	--	--	downlist	rad	Snapped variable for the star tracker vertical angle measurement (STAR TRCK SOP HAL name V_NAV, M/S ID # V95H4754C).
IQ_VERT	SF	local	--	--	--	rad	Measurement from vertical measurement sensor.
IR	DF(3)	local	--	--	--	ft	Temporary M50 position vector used in ACCEL_ONORBIT.
IRAD_PER_DEG	SF	compool	C	--	--	rad/deg	Conversion factor from degrees to radians.
IRANGE_AIF (V93J6241C)	C	compool	--	--	--	--	Auto/inhibit/force switch associated with the rendezvous radar range measurement.
IRANGE_AIF_DISPLAY (V90J1362C)	C	compool	--	--	downlist	--	Flag indicating to displays that the range auto/inhibit/force flag has been processed.
IRANGE_AIF_LAST	C	local	IV	inhibit	--	--	Last value of RANGE_AIF.

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
RANGE_EDIT_OVERRIDE	B	local	--	--	--	--	Flag indicating (ON) that the crew wishes to force rendezvous radar range measurement.
RANGE_STAT	B	local	--	--	--	--	Flag indicating (ON) that rendezvous radar range data is to be processed for statistical display only.
RDOT AIF (V93J6247C)	C	compool	--	--	--	--	Auto/inhibit/force switch associated with the rendezvous radar range rate measurement.
RDOT AIF DISPLAY (V90J1368C)	C	compool	--	--	downlist	--	Flag indicating to displays that the range rate auto/inhibit/force flag has been processed.
RDOT AIF_LAST	C	local	IV	inhibit	--	--	Last value of RDOT AIF.
RDOT DATA GOOD (V90X4900X)	B	compool	--	--	downlist	--	Snapped data validity flag for the rendezvous radar range rate measurement (RR SOP HAL name RR_RANGE_DG, M/S ID # V95X4294X).
RDOT_EDIT_OVERRIDE	B	local	--	--	--	--	Flag indicating (ON) that the crew wishes to force rendezvous radar range rate measurement.
RDOT_STAT	B	local	--	--	--	--	Flag indicating (ON) that rendezvous radar range rate data is to be processed for statistical display only.
IB_EP	DF(3)	local	--	--	--	ft	Earth fixed position vector used in ACCEL_ONORBIT.
REF ORB AREA (V96U9160C)	SF	compool	DD	2690.	--	ft ²	Orbiter reference cross sectional area used in propagation drag calculations.
REF ORB CD (V96U9161C)	SF	compool	DD	2.0	--	--	Orbiter reference drag coefficient.
REND_NAV_INIT_PRED	B	compool	IV	OFF	--	--	Flag indicating prediction task in progress as scheduled by REND_NAV_INIT.

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
REJ_MAX (V96U9162C)	I	local	DD	3	--	--	Maximum number of sequential marks; rejected by the residual edit test, before DISP_EDIT for the corresponding measurement is set to --.
REND_NAV_FLAG (V93X6220X)	B	compool	IV	OFF	downlist	--	Flag indicating whether rendezvous navigation (ON) or on-orbit navigation (OFF) is in operation.
REND_NAV_FLAG_LAST	B	local	IV	OFF	--	--	Last value of REND_NAV_FLAG.
RESID_RATIO_OLD	SF	compool	--	--	--	--	Value of residual ratio from the previous cycle for the measurement being processed.
RESID_TEST	SF	local	--	--	--	vary	Scaled value of the estimated measurement variance for comparison with the measurement deviation squared in the residual edit test.
RESID_TEST_RATIO	SF	compool	--	--	--	--	Ratio of the magnitude of the measurement residual and the scale value of the estimated measurement standard deviation to be used in the residual edit test.
R_FILT (V90H0584C -6C)	DF(3)	compool	--	--	--	1ft	Orbiter position vector (M50).
R_FILT_INIT (V90H1276C -8C)	DF(3)	compool	OPS	--	--	1ft	Orbiter position vector saved across memory reconfiguration and used for navigation initialization.
R_FILT_TLM (V90H4277C-79C)	DF(3)	compool	--	--	downlist	1ft	Orbiter position vector for downlist (M50).
R_FIN	DF(3)	local	--	--	--	1ft	Position vector at the end of a time interval in M50. Used in F & G series and in SUPER_G.
R_FIN_INV	DF	local	--	--	--	1ft ⁻¹	Reciprocal of the magnitude of R_FIN.

VARIABLES LIST

Variable name (M/S ID)	Preci- sion & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
IR_PIN_TEMP_INV	DF	local	--	--	--	ft ⁻¹	Dummy variable used in the call to F_AND_G.
IR_GHD (V96H3500C-02C)	DF(3)	compool	--	--	uplink	ft	Uplink Orbiter position vector in M50.
IRHO	SF	local	--	--	--	slugs/ft ³	Atmospheric density used in ACCEL_ONORBIT drag model.
IRHO_PLANE	SF(3)	local	--	--	--	ft	In-plane component of the line of sight.
IR_IN	DF(3)	local	--	--	--	ft	Position vector at the beginning of a time interval in M50. Used in F & G series and in SUPER_G.
IR_IN_INV	DF	local	--	--	--	ft ⁻¹	Reciprocal of the magnitude of IR_IN.
IR_INV	DF	local	--	--	--	1/ft	Inverse of M50 position used in ACCEL_ONORBIT.
IR_LAST (V90H4782C -4C)	DF(3)	compool	--	--	--	ft	Position vector of the Orbiter at the end of the last filter cycle (M50).
IRNG	SF	local	--	--	--	ft	Computed range measurement.
IRNG_DATA_GOOD (V90X4899X)	B	compool	--	--	downlist	--	Snapped data validity flag for range measurement (RR SOP HAL name RR_RNG_DG, M/S ID # V95X4293X).
IRNG_DOT	SF	local	--	--	--	ft/sec	Computed range rate measurement.
IRNG_MIN (V96U9163C)	SF	local	DD	1.0	--	ft	Minimum separation between the Orbiter and the target.
IR_O_N	DF	local	--	--	--	ft/sec ²	Distance term used in ACCEL_ONORBIT gravitational acceleration model.
IR_ONE	DF(3)	local	--	--	--	ft	Position vector at the beginning of an interpolation interval (M50).

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
R_ONE_INV	DF	compool	--	--	--	ft ⁻¹	Reciprocal of the magnitude of R_ONE.
RO_ZERO	DF	local	--	--	--	--	Distance term in ACCEL_ONORBIT gravitational acceleration model.
R_PRED_FINAL (V95B0811C -3C)	DF(3)	compool	--	--	downlist	ft	Position vector as output from precise state predictor (M50).
R_PRED_INIT (V94H4002C -4C)	DF(3)	compool	--	--	downlist	ft	Position vector input for prediction (M50).
RR_ANGLE_DATA_GOOD (V90X4901X)	B	compool	--	--	downlist	--	Snapped data validity flag for the rendezvous radar angles measurement (RR SOP HAL name RR_ANGLE_DG, M/S ID #V95X4295X).
RR_ANGLE_MARK_NUM (V90J4824C)	I	compool	IV	0	downlist	--	Rendezvous radar angle (shaft plus turnion) mark counter.
RR_ANGLES_BIAS_INIT (V96U9164C-5C)	SF(2)	local	MD	--	--	rad	Initial value for the rendezvous radar angles bias slot of the state vector.
RR_ANGLES_EDIT_ OVERRIDE	B	local	--	--	--	--	Flag indicating (ON) that the crew wishes to force rendezvous radar angles data.
RR_ANGLES_ENABLE (V93X6230X)	B	compool	--	--	--	--	Rendezvous radar angles enable flag.
RR_ANGLES_STAT	B	local	--	--	--	--	Flag indicating (ON) that rendezvous radar angles data is to be processed for statistical display only.
RRDOT_BIAS_INIT (V96U9166C-7C)	SF(2)	local	MD	--	--	ft, ft/sec	Initial value for the rendezvous radar range and range rate bias slots of the state vector.
RRDOT_MARK_NUM (V90J4825C)	I	compool	IV	0	downlist	--	Range and range rate data mark counter.

VARIABLES LIST

Variable name (M/S ID)	Preci- sion & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
IRREP (V96U9168C)	DF	local	DD	12.3769016 E-3	--	slugs/ft ³	Constant used to define units of density in ACCEL_ONORBIT drag model.
IR_RESET (V90H0235C -7C)	DF(3)	compool	--	--	--	ft	Orbiter position vector reserved for the reset of user parameter state propagation position vector (M50).
IR_RESID	DF(3)	local	--	--	--	ft	Orbiter position vector interpolated to measurement time (M50).
IR_RHO	SF(3)	compool	--	--	--	ft	Line of sight (M50).
IR_RHO_MAG	SF	compool	--	--	--	ft	Magnitude of the relative position vector.
IR_TV (V90H0307C -9C)	DF(3)	compool	MD	--	--	ft	Target vehicle M50 position vector.
IR_TV_GND (V96H1277C -9C)	DF(3)	compool	--	--	uplink	ft	Uplink target position vector in M50.
IR_TV_LAST (V90H4789C -91C)	DF(3)	compool	--	--	--	ft	Target position vector at the end of last filter cycle (M50).
IR_TV_RESET (V90H1363C -5C)	DF(3)	compool	--	--	--	ft	Target position vector reserved for the reset of user parameter state propagation position vector (M50).
IR_TV_RESID	DF(3)	local	--	--	--	ft	Target position vector interpolated to measurement time (M50).
IR_TV_TLM (V90H4287C-89C)	DF(3)	compool	--	--	downlist	ft	Target position vector for downlist (M50).
IR_TWO	DF(3)	local	--	--	--	ft	Position vector at the end of the interpolation interval (M50).

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
R_TWO_INV	DF	local	--	--	--	ft ⁻¹	Reciprocal of the magnitude of R_TWO.
IS	DF(9)	local	C	--	--	--	Tesseral harmonics coefficients used in ACCEL_ONORBIT gravitational acceleration.
IS	DF(6,6)	local	IV	0.	--	vary	State noise matrix for the covariance propagation.
SA	SP	local	--	--	--	--	Square of the sine of the angle of attack used in ACCEL_ONORBIT drag model.
SB	SP	local	--	--	--	--	Absolute value of the sine of side slip angle used in ACCEL_ONORBIT drag model.
IS_BIAS	DF(4)	local	--	--	--	(rad ² , irad ² , ft ² /sec ²)	State noise terms for the sensor bias slots.
SDEC	DF	compool	--	--	--	--	Sine of solar declination used in ACCEL_ONORBIT atmospheric density model.
SELF TEST FLAG (V90X488X)	B	compool	--	--	downlist	--	Snapped flag indicating that rendezvous radar is in the self-test mode. (RR SOP HAL name RR_SELF_TEST, M/S ID # V95X4309X.)
SENSOR_BIAS	SP(4)	compool	IV	0,0,0,0	--	rad,rad, ft,ft/sec	Sensor biases, part of state vector (M50).
SENSOR_BIAS_TLM (V90U4295C-98C)	SP(4)	compool	--	--	downlist	rad,rad, ft,ft/sec	Sensor biases (part of state vector) for TLM (M50).
SENSOR_DELQ	SP(4)	compool	--	--	--	vary	Measurement residuals.
SENSOR_DELTA	DF	local	DD	$1/\sqrt{3}$	--	--	An increment used to adjust the relative unit vector for measurement processing.

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
ISENSOR_EDIT (V90J8241C, V90J8880C-82C)	C(4)	compool	--	--	downlist	--	Five-valued parameter defining use of measurement data by the navigation filter. ON - rejected by the residual edit test OFF - no processing attempted PROCESSED - accepted by residual edit test and used to update the state vector STAT - used to generate display parameters FORCED - used to update state vector as a result of manual edit override
ISENSOR_EPS	DF	local	DD	--	--	ft	Minimum allowable distance between target and shuttle for measurement processing.
ISEQ_ACCEPT (V90J4732C, 33C, 30C, 31C)	I(4)	compool	IV	0	downlist	--	Number of sequential sensor marks accepted by the residual edit test for the various sensor measurements.
ISEQ_REJECT (V90J4737C, 38C, 35C, 36C)	I(4)	compool	IV	0	downlist	--	Number of sequential sensor marks rejected by the residual edit test for the various sensor measurements.
ISHAFT	SF	local	--	--	--	rad	Estimate of the rendezvous radar shaft measurement.
ISHUTTLE_FILTER_FLAG (V90X4952X)	B	compool	MD	--	downlist	--	Flag indicating which vehicle state is to be used by the filter; (ON) Shuttle state (OFF) target state.
ISIPST	SF	local	--	--	--	ft	Variable used in atmospheric density model in ACCEL_ORBIT.
ISIG_RR_RNG (V96U9168C)	SF	local	DD	0.	--	feet	One sigma statistic of rendezvous radar range measurement.
ISIG_UPDATE (V96H1284C-9C)	SF(6)	compool	MD	--	uplink	ft, ft/sec	Standard deviations (UVW) for the filter vehicle position/velocity covariance initialization.
ISIN_LAG (V96U9169C)	SF	local	DD	.601815023	--	--	Sine of atmospheric density bulge lag angle used in ACCEL_ORBIT.

A-40

VARIABLES LIST

Variable name (M/S ID)	Preci- sion & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
ISIN_SOL_RA	DF	compool	--	--	--	--	Sine of solar right ascension used in ACCEL_ONORBIT density model.
SLOPE SIG RR RMG (V9609170C)	SF	local	DD	3.E-3	--	--	Rate of change of rendezvous radar range statistics with respect to range.
ISMA	DF	compool	--	--	--	ft	Semimajor axis of conic.
SQR_EMU (V9001241C)	DF	compool	--	--	--	ft ^{3/2} /sec	Square root of EARTH_MU used in onorbit prediction/propagation equations of motion (Pines method).
ISSND	SF	local	--	--	--	ft	Variable used in ACCEL_ONORBIT atmospheric density calculation.
IST_ANGLES_BIAS_INIT (V9609171C-2C)	SF(2)	local	MD	--	--	rad	Initial value for the star tracker angles bias slots of the state vector.
IST_ANGLES_EDIT_ OVERRIDE	B	local	--	--	--	--	Flag used (ON) to override the residual edit test for star tracker angles data.
IST_ANGLES_STAT	B	local	--	--	--	--	Flag indicating (ON) that star tracker angles data are to be processed for statistical display only.
ISTAT_FLAG	C	compool	--	--	--	--	Copy of the stat flag associated with the measurement type currently being processed.
IST_DATA_GOOD (V90X4835X)	B	compool	--	--	downlist	--	Snapped data validity flag for Star tracker data (STAR TRCK SOP HAL name DATA_GOOD, M/S ID # V95X4771X).
IST_ENABLE (V93X6223X)	B	compool	--	--	--	--	Star tracker angle ENABLE flag.
IST_MARK_NUM (V90J4826C)	I	compool	IV	0	downlist	--	Star tracker measurement mark counter.

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
IS_UNMOD_ACC	DF(3,3)	local	--	--	--	ft ² /sec ⁴	Unmodeled acceleration noise terms.
ISV_TIME_TAG_DIFF	SF	local	HC	0.5	--	sec	Time tolerance used to test the time tag of the predicted state against the reset time tag of navigation.
ISV_UPDATE	B	local	--	--	--	--	A flag, local to the auto-inflight update subfunction, which indicates (ON) that a state vector update has occurred.
IS0	DF	local	--	--	--	--	Auxiliary variables used in F & G series and Pines computations, S1 & S2 also used as auxiliary variables in mean conic partials transition matrix computations.
IS1						vary	
IS2						vary	
IS3						vary	
IS2B	SF	local	--	--	--	--	Absolute value of sine of twice the side slip angle used in ACCEL_ONORBIT drag model.
IT	DF	local	--	--	--	sec	Time variable (GMT) used in ACCEL_ONORBIT.
TARGET AREA (V9609173C)	SF	compool	MD	--	--	ft ²	Target vehicle reference cross-sectional area.
TARGET CD (V9609174C)	SF	compool	MD	--	--	--	Target vehicle reference drag coefficient.
TARGET MASS (V9609175C)	SF	compool	MD	--	--	slugs	Target vehicle reference mass.
TAU	SF(2)	local	--	--	--	sec	Local variable for sensor time constants.
TAU COAS ANGLES (V9609176C-7C)	SF(2)	local	DD	1300., 1300.	--	sec	Time constant for the COAS angles sensor.
TAU RR ANGLES (V9609178C-9C)	SF(2)	local	DD	1.E6, 1.E6	--	sec	Correlation time constant for the rendezvous radar angle measurement.

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
TAU_RRDOT (V96U9180C-1C)	SF(2)	local	DD	1.E6,1.E9	--	!sec	ECRV correlation time vector for rendezvous radar range and range rate.
TAU_SENS	SF(4)	compool	IV	1.,1.,1.,1.	--	!sec	General correlation time constants for sensors.
TAU_ST ANGLES (V96U9182C-3C)	SF(2)	local	DD	1300., 1300.	--	!sec	Correlation time constant for star tracker measurements.
TAU_U A COAST (V96U9184C)	SF	compool	DD	300.	--	!sec	Correlation time constant for unmodeled accelerations during coasting flight.
TAU_U A PWRD FLT (V96U9185C)	SF	local	DD	300.	--	!sec	Correlation time constant for unmodeled accelerations during powered flight.
TAU_UNMOD ACC COV (V96U9186C)	SF	compool	DD	300.	--	!sec	Correlation time constant for unmodeled accelerations used in covariance propagation.
TAU_UNMOD ACC STATE (V96U9186C)	SF	local	DD	300.	--	!sec	Correlation time constant for unmodeled accelerations used in state propagation.
T_BIAS COAS (V96U9187C)	SF	local	DD	0.	--	!sec	Time tag bias associated with COAS measurements.
T_BIAS RENOV RADAR (V96U9188C)	SF	local	DD	0.	--	!sec	Time tag bias associated with rendezvous radar measurements.
T_BIAS ST (V96U9189C)	SF	local	DD	0.	--	!sec	Time tag bias associated with star tracker measurements.
T_COAS (V96U9189C)	DF	compool	--	--	downlist	!sec	Snapped variable for the COAS measurement time tag (STAN TRCK SOP HAL name T_TANLOS, M/S ID # V95U9185C).
T_COAS_LAST	DF	local	IV	0.	--	!sec	Time of last COAS measurement update.
T_COV_LAST (V96U91771C)	DF	compool	--	--	--	!sec	Time tag of last covariance propagation.

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
T_CUR	DF	local	--	--	--	sec	Current integration time within the predictor or propagator.
T_CURRENT_FILT (V90M4749C)	DF	compool	--	--	downlist	sec	Snapped time tag of the current IMU/ATT data (IMU SOP HAL name T_IMES_GA, M/S ID # V95M0002C).
IDV_FILT	SP(3)	local	HC	0,0,0	--	ft/sec	Funny vector for target accumulated velocity.
TEMP	DF(13,13)	local	--	--	--	vary	Temporary matrix used during covariance matrix propagation to store the intermediate calculation of E_0^T during the $\phi E_0^T + S$ computation.
TEMP	DF(3)	local	--	--	--	sec/feet	Temporary vector used by the mean conic partial.
TEST_VALUE	SP	local	--	--	--	--	Value against which the residual ratio is tested. If the residual ratio is greater than TEST_VALUE, the measurement is edited.
T_FILT_INIT (V90M1287C)	DF	compool	GPS	--	--	sec	Time tag of navigation initialization data carried across memory transition.
T_FIN	DF	local	--	--	--	sec	Final time at end of prediction or propagation, used in SUPER_G.
TPOFF (V96M8178C) (V90M4960C)	DF	compool	MD	--	uplink, downlist	sec	Vent/RCS thrust force off time used in ACCEL_ORBIT.
TPON (V96M8177C) (V90M4959C)	DF	compool	MD	--	uplink, downlist	sec	Vent/RCS thrust force on time used in ACCEL_ORBIT.
T_GND (V96M3520C)	DF	compool	--	--	uplink	sec	Uplinked time tag of Orbiter state vector.
THETA	DF	local	--	--	--	rad	Difference of eccentric anomaly.

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
THETA_COR	DF	local	--	--	--	rad	Correction to THETA in the solution of Kepler's equation, used in P and G.
T_IN	DF	local	--	--	--	sec	Initial time input for state propagation, used in SUPER_G.
T_LAST_FILT (V90W1252C)	DF	compool	--	--	--	sec	Time tag of V_LAST_FILT and of filter state at last navigation cycle.
T_LAST_FILT_TLM (V90W4285C)	DF	compool	--	--	downlist	sec	Time tag of Orbiter and target state vector at last navigation cycle (for TLM)
T_ORB_STATE_UPDATE (V94W3727C)	DF	compool	MD	--	downlist	sec	Time tag of most recent Orbiter state vector update (for TLM).
TOT_ACC (V90A4874C-76C)	DF(3)	compool	--	--	downlist	ft/sec ²	Orbiter M1950 total acceleration vector.
TOT_ACC_LAST (V90A1962C-4C)	DF(3)	compool	--	--	--	ft/sec ²	Value of TOT_ACC at the end of the previous cycle.
T_PRED_FINAL (V94W3979C)	DF	compool	--	--	downlist	sec	Time tag for prediction (associated with R_PRED_FINAL and V_PRED_FINAL).
T_PRED_INIT (V94W3970C)	DF	compool	--	--	downlist	sec	Time tag for prediction (associated with R_PRED_INIT and V_PRED_INIT).
T_REND_RADAR (V90W4841C)	DF	compool	--	--	downlist	sec	Snapped time tag of the rendezvous radar measurement (RR SOP HAL name RR_TIM, M/S ID # V95W4292C).
T_RESET (V90W0225C)	DF	compool	--	--	--	sec	Time associated with reserved reset state.
T_RESID	DF	local	--	--	--	sec	Time tag of interpolated state vector.
TRG_TRK_MODE (V90U4836C)	B	compool	--	--	downlist	--	Snapped flag indicating (ON) that the star tracker is in the target tracking mode (STAR TRCK SOP HAL name NAV_TARGET, M/S ID # V95X4778X).

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
ITRUN	SF	local	--	--	--	rad	Estimate of the rendezvous radar trunnion angle measurement.
IT_STAR_TRACKER (V90U4837C)	DF	compool	--	--	downlist	sec	Snapped variable for the star tracker measurement time tag (STAR TRCK SOP HAL name TIME, M/S ID # V95W4760C).
IT_ST_LAST	DF	local	IV	0.	--	sec	Time of last star tracker measurement.
IT_TV (V90W0315C)	DF	compool	MD	--	downlist	sec	Target vehicle state vector time tag.
IT_TV_GND (V96W1283C)	DF	compool	--	--	uplink	sec	Uplinked target state time tag.
IT_TV_STATE_UPDATE (V90W4939C)	DF	compool	MD	--	downlist	sec	Time tag of most recent target state vector update (for TLM).
ITV_PREDICT_FAIL (V90X4769XA)	B	compool	--	--	downlist	--	Flag which indicates that the time tolerance MAX_TIME_TOL has been exceeded and consequently no target state vector prediction will take place.
IU_M	SF(3)	compool	--	--	--	feet	Line of sight vector in sensor system.
IUNMOD_ACC_BIAS (V90U1265C -7C)	SF(3)	compool	--	--	--	ft/sec ²	Unmodeled acceleration bias.
IUNMOD_ACC_BIAS_TLM (V90U4301C-03C)	SF(3)	compool	--	--	downlist	ft/sec ²	Unmodelled acceleration bias for TLM.
IUNMOD_ACC_UPDATE_FLAG (V96U9190C)	B	local	MD	--	--	--	Flag indicating (ON) that the unmodeled acceleration bias states are to be updated by the filter.
IUR	DF(3)	local	--	--	--	--	Earth fixed unit vector used in ACCEL_ONORBIT drag model.
IU_RDOT	SF(3)	local	--	--	--	1/sec	Local variable used in the calculation of the estimated range rate measurement.
IUR_SUN	DF(3)	compool	--	--	--	--	Sun unit vector in M50 coordinates.

A-46

VARIABLES LIST

Variable name (M/S ID)	Preci- sion & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
USE IMU DATA (V90X0538X)	B	compool	IV	OFF	downlist	--	Flag indicating (ON) the usage of IMU data by the powered flight propagator.
V	DF(3)	local	--	--	--	ft/sec	Vehicle M50 velocity used in ACCEL_ONORBIT.
IVAR	SF	compool	--	--	--	vary	Copy of variance associated with measurement currently being processed.
IVAR COAS ANGLES (V96U9191C-2C)	SF(2)	local	DD	4.E-6, 4.E-6	--	rad ²	COAS angles measurement bias variables used to initialize the covariance matrix.
IVAR COAS HORIZ (V96U9193C)	SF	local	DD	4.E-8	--	rad ²	Variance of the COAS horizontal measurement.
IVAR COAS VERT (V96U9194C)	SF	local	DD	4.E-8	--	rad ²	Variance of the COAS vertical measurement.
IVAR_HORIZ	SF	local	--	--	--	rad ²	Variance of the horizontal measurement sensor.
IVAR IMU ALIGN (V96U9195C)	SF	local	DD	.1	--	rad ²	Variance of platform misalignment added as process noise in the covariance matrix.
IVAR RANGE DOT (V96U9196C)	SF	local	DD	1.0	--	ft ² /sec ²	Variance of the rendezvous radar range rate sensor measurement.
IVAR RR ANGLES (V96U9197C-8C)	SF(2)	local	DD	3.E-4, 3.E-4	--	rad ²	Rendezvous radar angles measurement bias variances used to initialize the covariance matrix.
IVAR RR DOT (V96U9199C-200C)	SF(2)	local	DD	11.0, 1.0	--	ft ² / sec ²	Rendezvous radar range and range rate measurement bias variance used to initialize the covariance matrix.
IVAR RR RNG_MIN (V96U9201C)	SF	local	DD	711.	--	ft ²	Minimum value for computation of rendezvous radar range variance.

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
IVAR_SENS	SF(4)	compool	--	--	--	vary	General measurement bias filter variance used in propagation of sensor biases and in adding process noise.
IVAR SHAFT (V96U9202C)	SF	local	DD	1.1 E-5	--	rad ²	Variance of the rendezvous radar shaft angle measurement.
IVAR ST ANGLES (V96U9203C-4C)	SF(2)	local	DD	1.2E-6, 1.2E-6	--	rad ²	Star tracker angles measurement bias variances used to initialize the covariance matrix.
IVAR ST HORIZ (V96U9205C)	SF	local	DD	1.0 E-8	--	rad ²	Variance of star tracker horizontal angle measurement.
IVAR ST VERT (V96U9206C)	SF	local	DD	1.0 E-8	--	rad ²	Variance of star tracker vertical angle measurement.
IVAR TRUN (V96U9207C)	SF	local	DD	1.1 E-5	--	rad ²	Variance of the rendezvous radar trunnion angle measurement.
IVAR U A COAST (V96U9208C-10C)	SF(3)	compool	DD	13*3.E-10	--	ft ² /sec ⁴	Variance of unmodeled accelerations during coasting flight.
IVAR U A PWRD FLT (V96U9211C-13C)	SF(3)	local	DD	13*E-2	--	ft ² /sec ⁴	Variance of unmodeled accelerations during powered flight.
IVAR UNMOD ACC (V90A4933C-35C)	SF(3)	compool	--	--	--	ft ² /sec ⁴	Variance of unmodeled accelerations.
IVAR_VERT	SF	local	--	--	--	rad ²	Variance of the vertical measurement sensor.
IV CURRENT FILT (V90L8927C -9C)	DP(3)	compool	--	--	downlist	ft/sec	Snapped variable for the total accumulated IMU sensed velocity (IMU RM HAL name V_IMU_CURRENT, M/S ID # V90L2557C-9C).
IVEH MASS	SF	local	--	--	--	slugs	Vehicle mass used in ACCEL_ONORBIT drag model.
IVENT	SF(3)	local	--	--	--	ft/sec ²	Vent/RCS thrust acceleration used in ACCEL_ONORBIT.
IVENT_SS (V90U4964C-66C)	SF(3)	compool	--	--	downlist	ft/sec ²	Orbiter vent vector for downlist.

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
IVERT	SF	local	--	--	--	rad	Filter estimated vertical angle measurement.
IV_FILT (V90L0624C -6C)	DP(3)	compool	--	--	--	lft/sec	Orbiter M1950 velocity vector.
IV_FILT_INIT (V90L1279C -81C)	DP(3)	compool	OPS	--	--	lft/sec	Orbiter velocity vector saved across memory reconfiguration and used for navigation initialization.
IV_FILT_TLM (V90L4281C-83C)	DP(3)	compool	--	--	downlist	lft/sec	Orbiter velocity vector for TLM (M50).
IV_FIN	DP(3)	local	--	--	--	lft/sec	Orbiter or target velocity vector at T_FIN, used in SUPER_G.
IVFL_OV	B	compool	HC	1	--	--	Flag indicating activation (1) or deactivation (0) of Vent/RCS thrust acceleration models for Orbiter propagation.
IVFLOV_PRED	B	compool	HC	0	--	--	Flag indicating activation (1) or deactivation (0) of Vent/ RCS thrust acceleration model for Orbiter prediction.
IVFL_TV	B	compool	HC	1	--	--	Flag setting that specifies use of unmodeled acceleration bias for target vehicle propagation.
IVFLTV_PRED	B	compool	HC	0	--	--	Flag setting that specifies use of unmodeled acceleration bias for target vehicle prediction.
IVFORCE (V96U8174C-76C) (V90U4956C-58C)	SP(3)	compool	MD	--	Uplink, downlist	lbs.	Vent/RCS thrust force vector in body coordinates used in ACCEL_ONORBIT.
IV_GND (V96L3510C-12C)	DP(3)	compool	--	--	uplink	lft/sec	Uplinked Orbiter velocity vector.
IV_IMU_DIF	DP(3)	local	--	--	--	lft/sec	Difference in current and past accumulated sensed IMU velocities used in state vector interpolation.
IV_IMU_RESET (V90L0247C -9C)	DP(3)	compool	--	--	downlist	lft/sec	Copy of V_LAST_FILT.

VARIABLES LIST

Variable name (M/S ID)	Preci- sion & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
IV_IN	DP(3)	local	--	--	--	ft/sec	Orbiter or target velocity vector at T_IN used in P & G or SUPER_G.
IV_LAST (V90L4785C -7C)	DP(3)	compool	--	--	--	ft/sec	Velocity vector of the Shuttle at the end of the last filter subcycle.
IV_LAST_FILT (V90L0621C -3C)	DP(3)	compool	--	--	--	ft/sec	Total accumulated IMU sensed velocity.
IVM	B	local	--	--	--	--	Flag used in ACCEL_ONORBIT to indicate if Vent/RCS model is to be used.
IVMP (V94X3971X)	B	compool	--	--	--	--	Flag indicating use or nonuse of the vent model in prediction.
IV_ONE	DP(3)	local	--	--	--	ft/sec	Velocity vector at the beginning of a time interval used to generate a transition matrix.
IV_PRED_FINAL (V95L0814C -6C)	DP(3)	compool	--	--	downlist	ft/sec	Velocity vector as output from precision state predictor.
IV_PRED_INIT (V94L4006C -8C)	DP(3)	compool	--	--	downlist	ft/sec	Initial velocity vector for prediction.
IV_R	SP(3)	local	--	--	--	ft/sec	Velocity of vehicle relative to atmosphere used in ACCEL_ONORBIT drag model.
IV_REL_BODY	SP(3)	local	--	--	--	ft/sec	Orbiter velocity relative to the atmosphere.
IV_RESET (V90L0239C -41C)	DP(3)	compool	--	--	--	ft/sec	Orbiter vehicle velocity vector after all navigation updates reserved for reset of user parameter state propagator velocity vector.
IV_RESID	DP(3)	local	--	--	--	ft/sec	M1950 velocity vector interpolated to the measurement time.

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
IV_RHO	SF(3)	compool	--	--	--	ft/sec	Relative M1950 velocity vector.
IV_TV (V90L0310C -12C)	DF(3)	compool	MD	--	--	ft/sec	Target vehicle M1950 velocity vector.
IV_TV_GND (V96L1280C -2C)	DF(3)	compool	--	--	uplink	ft/sec	Uplinked target velocity vector.
IV_TV_LAST (V90L4792C -1C)	DF(3)	compool	--	--	--	ft/sec	Last value of the target vehicle velocity vector.
IV_TV_RESET (V90L1380C -2C)	DF(3)	compool	--	--	--	ft/sec	Target vehicle velocity vector after all navigation updates, reserved for reset of user parameter state propagator velocity vector.
IV_TV_RESID	DF(3)	local	--	--	--	ft/sec	Velocity vector of the target vehicle at measurement time.
IV_TV_TLM (V90L4291C -93C)	DF(3)	compool	--	--	downlist	ft/sec	Target velocity vector for TLM (M50).
IV_TWO	DF(3)	local	--	--	--	ft/sec	Velocity vector at the end of a time interval used to generate a transition matrix.
WT_DISP (V93G6940C)	SF	compool	OPS	--	--	lbs	Displayed weight transferred from OPS 1 to OPS 2, or OPS 3 to OPS 2.
IX	DF(6)	local	--	--	--	ft,ft,ft, ft/sec, ft/sec, ft/sec	Temporary array for the Orbiter or target state vector, used in Pines method.
IXN	DF(7)	local	--	--	--	ft,ft,ft, ft/sec, ft/sec, ft/sec, sec	Array of integrated initial conditions for onorbit prediction and propagation.

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initialization category	Initial value	Uplink/downlist	Units	Description
ZETA_IMAG	DF(5)	local	--	--	--	--	Coefficients used in ACCEL_ONORBIT gravitational acceleration which are longitude dependent.
ZETA_REAL	DF(5)	local	--	--	--	--	Coefficients used in ACCEL_ONORBIT gravitational acceleration which are longitude dependent.
ZONAL	DF(4)	local	C	--	--	--	Zonal harmonics coefficients used in ACCEL_ONORBIT gravitational acceleration.

IN LIST: GMD, GMD, DM, VM, ATM, R, Y, T

GMD CONTROLS THE DEGREE OF THE GRAVITY MODEL.
 GMD CONTROLS THE ORDER OF THE GRAVITY MODEL.
 DM CONTROLS THE USE OR NONUSE OF DRAG ACCELERATION MODEL.
 VM CONTROLS THE USE OR NONUSE OF VENTING AND UNCOUPLED THRUSTING MODEL.
 ATM CONTROLS THE INCORPORATION OF UNMODELED ACCELERATIONS (IN CONJUNCTION WITH THE SHUTTLE_FILTER_FLAG) AND WHEN COMPUTING DRAG, THE VARIOUS DRAG MODEL OPTIONS USED (I.E., CURRENT ATTITUDE, AREA, DRAG COEFFICIENT, ETC.).
 R, Y ARE THE POSITION AND VELOCITY VECTORS OF THE VEHICLE IN MSO COORDINATES.
 T IS THE TIME IN GMT SECONDS.

VARIABLE LIST

PRECEDING PAGE BLANK NOT FILMED

VARIABLES LIST DEFINITIONS

CODE USED FOR VARIABLE DATA TYPE

- F: floating point quantity; an n-dimensional floating point vector will be denoted $F(n)$; similarly, an $n \times m$ floating point matrix will be denoted by $F(n,m)$
- I: integer quantity; $I(n)$ will denote an n-dimensional integer vector
- B: bit, i.e., data having only values of 0 or 1
- C: character; $C(n)$ will denote an n-dimensional character string

CODE USED FOR VARIABLE PRECISION

- D: double precision
- S: single precision; integer quantities are assumed single precision unless otherwise specified

VARIABLE LOCATION

- COMPOOL: Variable value located in common storage, accessible by all functions
- LOCAL : Variable is used by one function only, and usable to other functions through call argument only

VARIABLE INITIALIZATION CATEGORY

- blank: display is vacant
- C: constant (unchanging)
- DD: design dependent
- HC: hard coded
- MD: mission dependent (I-LOAD)

VARIABLE INITIAL VALUE

initial operation sequence computer inputs

VARIABLE UPLINK AND DOWNLIST STATUS

UPLINK: variable is an uplink item

DOWNLIST: variable is a downlist item

UNITS DEFINITIONS

deg: angular measurement, degrees

ft: feet

lb: pounds

n.d. (or -) non-dimensional

rad: radian

sec: time measurement, seconds

slugs: mass measurement, slugs

vary: units have different values which depend on variable use

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
A	SF(3,3)	local	-	-	-	-	Temporary matrix used in QUAT_TO_MAT
AA (V96U9057C-60C)	DF(4)	local	DD	$\frac{1}{2}$ $1 - \sqrt{1/2}$ $1 + \sqrt{1/2}$ $1/6$	-	-	Array of coefficients required by the RK_GILL integrator
ALT	DF	local	-	-	-	ft	Current Orbiter altitude above reference ellipsoid
A_O	DF	local	-	-	-	-	One minus eccentricity squared of Earth (ellipsoid), 1.0-PLATCON, initialized only
ATM	I	local	-	-	-	-	Flag indicating if current or prestored configuration constants are to be used in drag computations within ACCEL_ORBIT
ATMP (V94J3999C)	I	compool	-	-	downlist	-	Flag indicating vehicle attitude mode to be used for prediction
AZ	SF	local	-	-	-	rad	Bearing from true north (EF_TO_RUNWAY, EF_TO_SCANNER)
BB (V96U9080C-3C)	DF(4)	local	DD	0. 1. 1. 2.	-	-	Array of coefficients used by the RK_GILL integrator
CAZ	SF	local	-	-	-	-	Cosine of AZ
CC (V96U9090C-3C)	DF(4)	local	DD	1. $12(1-\sqrt{1/2})$ $12(1+\sqrt{1/2})$ 0.	-	-	Array of coefficients used by the RK_GILL integrator
CLAT	SF	local	-	-	-	-	Cosine of LAT_GEO (EF_TO_TOPDET)
CLON	SF	local	-	-	-	-	Cosine of LON (EF_TO_TOPDET)
CGS_P	SF	local	-	-	-	-	Cosine of geocentric latitude to Shuttle

COORDINATE SYSTEMS

NAME: Aries mean of 1950, Cartesian, coordinate system

ORIGIN: The center of the Earth

ORIENTATION: The epoch is the beginning of Besselian Year 1950 or Julian ephemeris date 2433282.423357.

The X_M - Y_M plane is the mean Earth's equator of epoch.

The X_M axis is directed toward the mean vernal equinox of epoch.

The Z_M axis is directed along the Earth's mean rotational axis of epoch and is positive north.

The Y_M axis completes a right-handed system.

CHARACTERISTICS: Inertial, right-handed Cartesian system.

Figure C-1.- Aries Mean of 1950, Cartesian.

NAME: Earth fixed (Greenwich true of date) coordinate system

ORIGIN: The center of the Earth

ORIENTATION: The X_G - Y_G plane is the Earth's true-of-date equator.

The Z_G axis is directed along the Earth's true-of-date rotational axis and is positive north.

The $+X_G$ axis is directed toward the prime meridian.

The Y_G axis completes a right-handed system.

CHARACTERISTICS: Rotating, right-handed Cartesian. Velocity vectors expressed in this system are relative to a rotating reference frame fixed to the Earth, whose rotation rates are expressed relative to the Aries mean of 1950 system.

Figure C-2.- Earth-Fixed Greenwich True of Date.

NAME: Aries true of date, Cartesian, coordinate system

ORIGIN: The center of the Earth

ORIENTATION: The epoch is the current time of interest.

The X_{TR} - Y_{TR} plane is the Earth's true equator of epoch.

The X_{TR} axis is directed toward the true vernal equinox of epoch.

The Z_{TR} axis is directed along the Earth's true rotational axis of epoch and is positive north.

The Y_{TR} axis completes the right-handed system.

CHARACTERISTICS: Quasi-inertial, right-handed Cartesian

Figure C-3.- Aries True of Date, Cartesian.

- NAME:** Geodetic parameters
- ORIGIN:** This system consists of a set of parameters rather than a coordinate system; therefore, no origin is specified.
- ORIENTATION:** This system of parameters is based on an ellipsoidal model of the Earth (e.g., the Fischer ellipse of 1960). For any point of interest we define a line known as the geodetic local vertical which is perpendicular to the ellipsoid and which contains the point of interest.
- h , geodetic altitude, is the distance from the point of interest to the reference ellipsoid, measured along the geodetic local vertical, and is positive for points outside the ellipsoid.
- λ is the longitude measured in the plane of the Earth's true equator from the Prime (Greenwich) Meridian to the local meridian, measured positive eastward.
- ϕ_D is the geodetic latitude, measured in the plane of the local meridian from the Earth's true equator to the geodetic local vertical, measured positive north from the equator.
- CHARACTERISTICS:** Rotating polar coordinate parameters. Only position vectors are expressed in this coordinate system. Velocity vectors should be expressed in the Aries mean of 1950 or the Aries true-of-date polar for inertial or quasi-inertial representations, respectively.

Figure C-4.- Geodetic Parameters (Basic Definitions) (Sheet 1 of 2)

NAME: Geodetic parameters

DEFINITIONS:

- h is the altitude of Point P, measured perpendicular from the surface of the referenced ellipsoid.
- ϕ_D is the geodetic latitude of Point P.
- ϕ_C is the geocentric latitude of Point P.
- δ is the angle between radius vector and equatorial plane (declination).
- λ is the longitude of Point P. Angle (+ east) between plane of the figure and the plane formed by the Greenwich Meridian.

Figure C-4.- Geodetic Parameters (Detailed Explanation) (Sheet 2 of 2).

NAME:	Runway coordinate system
ORIGIN:	Runway center at approach threshold
ORIENTATION AND DEFINITIONS:	<p>Z_{LF} axis is normal to the ellipsoid model through the runway centerline at the approach threshold and positive toward the center of the Earth.</p> <p>X_{LF} axis is perpendicular to the Z_{LF} axis and lies in a plane containing the Z_{LF} axis and the runway centerline (positive in the direction of landing).</p> <p>Y_{LF} axis completes the right-handed system.</p> <p>A_{LF} is the runway azimuth measured in the $X_{LF}Y_{LF}$ plane from true north to the $+X_{LF}$ axis (positive clockwise).</p>
CHARACTERISTICS:	Rotating, Earth-referenced

Figure C-5.- Runway Coordinate System.

NAME: Topodetic coordinate system

ORIGIN: Orbiter center of mass*

ORIENTATION: Z_{TD} is normal to a geodetic local tangent plane and is positive toward the Earth's center.

X_{TD} is perpendicular to Z_{TD} axis and is positive northward along the meridian plane containing the Orbiter.

Y_{TD} completes the right-handed orthogonal system.

CHARACTERISTICS: Rotating, right-handed Cartesian system. Velocity vectors are expressible in this system for the Orbiter, given relative velocity V_{TD} in this system.

$$\gamma_{TD} = \sin^{-1} \left(\frac{-\dot{Z}_{TD}}{V_{TD}} \right)$$

$$\psi_{TD} = \tan^{-1} \left(\frac{\dot{Y}_{TD}}{\dot{X}_{TD}} \right)$$

ϕ_D = geodetic latitude

*A similar system may be defined for any point of interest.

Figure C-6.- Topodetic Coordinate System.

NAME:	MSBLS radar coordinate system
ORIGIN:	MSBLS radar position
ORIENTATION AND DEFINITIONS:	<p>Z_{RAD} is normal to the ellipsoidal model, positive away from the center of the Earth.</p> <p>X_{RAD} is in the local horizontal plane of the radar in the boresight direction of the radar antenna. The angle A_Z is measured positively clockwise from true north to X_{RAD}.</p>
CHARACTERISTICS:	Rotating, Earth-referenced

Figure C-7.- MSBLS Radar Coordinate System.

NAME: Body coordinate system (structural)

ORIGIN: In the Orbiter plane of symmetry, 400 inches below the centerline of the payload bay and at Orbiter X-station = 0

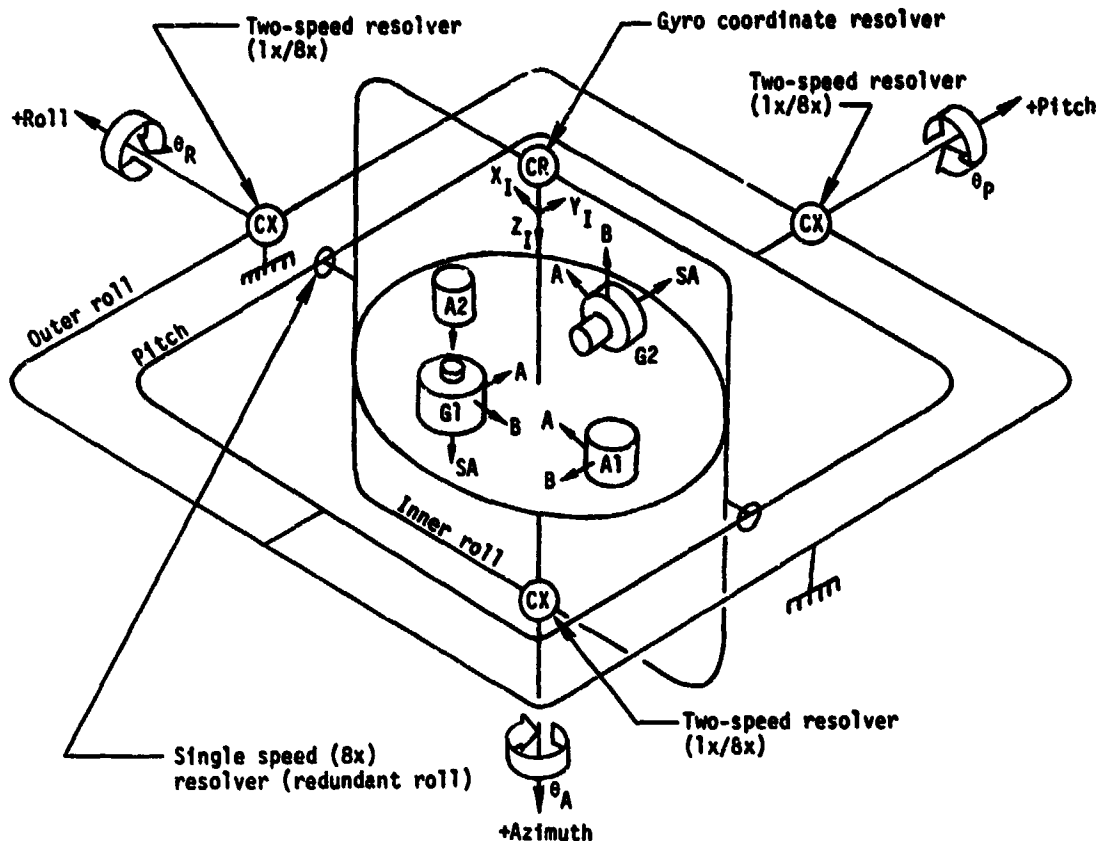

ORIENTATION: The X_0 axis is in the vehicle plane of symmetry, parallel to and 400 inches below the payload bay centerline. Positive sense is from the nose of the vehicle toward the tail.

The Z_0 axis is in the vehicle plane of symmetry, perpendicular to the X_0 axis and positive upward in landing attitude.

The Y_0 axis completes a right-handed system.

CHARACTERISTICS: Rotating, right-handed Cartesian

Figure C-8.- Body Coordinate System (Structural).

NAME: Stable member (IMU)

ORIGIN: The intersection of the innermost gimbal axis and the measurement plane of the XY two-axis accelerometer

ORIENTATION: The Z_I axis is coincident with the innermost gimbal axis.

The X_I axis is determined by the projection of the X accelerometer input axis (IA) onto a plane orthogonal to Z_I . Y_I completes a right-handed triad.

In a perfect IMU, with all misalignments zero, these relationships hold:

The X accelerometer and X gyro IA's are parallel to the X_I axis.

The Y accelerometer and Y gyro IA's are parallel to the Y_I axis.

The Z accelerometer and Z gyro IA's are parallel to the Z_I axis.

Figure C-9.- Stable Member (IMU) (Sheet 1 of 2).

CHARACTERISTICS: Nonrotating, right-handed, Cartesian system

The reference alinement for the gimbal case is defined with the four gimbal angles at zero and with the vehicle in a horizontal position. In a perfect IMU, with all misalignments zero and with all gimbal angles at zero, the following relationships hold.

X_{NB} , Y_{NB} , Z_{NB} are Cartesian components of the navigation base coordinate system.

The outer roll axis and the X_I -axis will be parallel to X_{NB} . Positive X_I will be in the forward direction. Positive roll gimbal angles will be in the sense of a right-handed rotation of the gimbal case relative to the platform about the plus outer roll axis.

The pitch axis and Y_I will be parallel to Y_{NB} . Positive Y_I will be to the right of an observer looking forward in the vehicle. Positive pitch gimbal angles will be in the sense of a right-handed rotation of the gimbal case relative to the platform about the plus pitch axis.

The inner roll axis will be parallel to the outer roll axis, with the sense of rotation the same as for the outer roll axis.

The azimuth axis and Z_I will be parallel to Z_{NB} . Positive Z_I will be down, relative to an observer standing in the vehicle. Positive azimuth gimbal angles will be in the sense of a right-handed rotation of the gimbal case relative to the platform about the plus azimuth axis.

Figure C-9.- Stable Member (IMU) (Sheet 2 of 2).

NAME: NWU geographic coordinate system

ORIGIN: Point of interest

ORIENTATION: U is positive up along the Earth's astronomic or plumb-bob vertical.

W is positive along the cross product of U and the Earth's spin axis.

N completes the right-handed orthogonal system
($N = W \times U$).

CHARACTERISTICS: Rotating, right-handed, Earth-referenced coordinate system

Figure C-10.- NWU Geographic Coordinate System.

- NAME:** Body axis coordinate system
- ORIGIN:** Center of mass
- ORIENTATION:** X_{BY} axis is parallel to the Orbiter structural body X_0 axis, positive toward the nose.
- Z_{BY} axis is parallel to the Orbiter plane of symmetry and is perpendicular to X_{BY} , positive down with respect to the Orbiter fuselage.
- Y_{BY} axis completes the right-handed orthogonal system.
- CHARACTERISTICS:** Rotating, right-handed, Cartesian system
- L, M, N: Moments about X_{BY} , Y_{BY} , and Z_{BY} axes, respectively
- p, q, r: Body rates about X_{BY} , Y_{BY} , and Z_{BY} axes, respectively
- \dot{p} , \dot{q} , \dot{r} : Angular body acceleration about X_{BY} , Y_{BY} , and Z_{BY} axes, respectively
- The Euler sequence that is commonly associated with this system is a yaw, pitch, roll sequence, where ψ = yaw, θ = pitch, and ϕ = roll or bank. This attitude sequence is yaw, pitch, and roll around the Z_{BY} , Y_{BY} , and X_{BY} axes, respectively.

Figure C-11.- Body Axis.

NAME: UVW coordinate system

ORIGIN: Point of interest

ORIENTATION: The U-V plane is the instantaneous orbit plane at epoch.

The U axis lies along the geocentric radius vector to the vehicle and is positive radially outward.

The W axis lies along the instantaneous orbital angular momentum vector at epoch and is positive in the direction of the angular momentum vector.

The V axis completes a right-handed system ($V = W \times U$).

CHARACTERISTICS: Quasi-inertial, right-handed Cartesian coordinate system. This system is quasi-inertial in the sense that it is treated as an inertial coordinate system, but it is redefined at each point of interest.

Figure C-12.- UVW Coordinate System

FLOWCHARTS

$$\text{EARTH_FIXED_TO_M50_COORD}(\text{TIME}) = \text{M_M50TOEF_AT_EPOCH}^T(\text{M})$$

WHERE:

M_M50TOEF_AT_EPOCH IS THE TRANSFORMATION FROM MEAN OF 1950 TO EARTH-FIXED COORDINATES AT TIME = T_EPOCH. THIS MATRIX, T_EPOCH, AND EARTH_RATE INITIAL VALUES ARE DISCUSSED IN SECTION 4.10.2.

M IS COMPUTED WITHIN THE FUNCTION (EARTH_FIXED_TO_M50_COORD) AS

$$\text{LAM} = \text{EARTH_RATE}(\text{TIME} - \text{T_EPOCH})$$

$$\text{M} = \begin{pmatrix} \cos(\text{LAM}) & -\sin(\text{LAM}) & 0 \\ \sin(\text{LAM}) & \cos(\text{LAM}) & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

VARIABLES LIST DEFINITIONS**CODE USED FOR VARIABLE DATA TYPE**

F: floating point quantity; an n-dimensional floating point vector will be denoted $F(n)$; similarly, an $n \times m$ floating point matrix will be denoted by $F(n,m)$

I: integer quantity; $I(n)$ will denote an n-dimensional integer vector

B: bit, i.e., data having only values of 0 or 1

C: character. $C(n)$ will denote an n-dimensional character string

CODE USED FOR VARIABLE PRECISION

D: double precision

S: single precision; integer quantities are assumed single precision unless otherwise stated

VARIABLE LOCATION

COMPOOL: Variable value located in common storage, accessible by all functions

LOCAL: Variable is used by one function only, and usable to other functions through call argument only

VARIABLE INITIALIZATION CATEGORY

blank: display is vacant

C: constant (unchanging)

DD: design dependent

HC: hard coded

MD: mission dependent (I-LOAD)

PRECEDING PAGE BLANK NOT FILMED

VARIABLE INITIAL VALUE

initial operation sequence computer inputs

VARIABLE UPLINK AND DOWNLIST STATUS

UPLINK: variable is an uplink item

DOWNLIST: variable is a downlist item

UNITS DEFINITIONS

deg: angular measurement, degrees

ft: feet

lb: pounds

n.d.: non-dimensional

rad: radian

sec: time measurement, seconds

slugs: mass measurement, slugs

vary: units have different values which depend on variable use

VARIABLES LIST

Variable name (M/3 ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
AC	SP (3)	local	--	--	--	ft/sec ²	Sensed acceleration (local variable used in AVERAGE_G_INTEGRATOR).

EVENT 83 (TBD)	B	compool	--	OFF	downlist	--	Transition from MM201 to OPS 00.
EVENT 84 (V90X8148X)	B	compool	--	OFF	downlist	--	Transition to MM201 from OPS 00 event.
IFILT UPDATE (V90X0224X)	B	compool	--	OFF	downlist	--	Flag indicating the availability of a filter updated state.
IGH_DEG LOW (V96U9118C)	I	compool	DD	2	--	--	Prestored value of potential model degree indicator.
IGH_ORD LOW (V96U9120C)	I	compool	DD	0	--	--	Prestored value of potential model order indicator.
IGR	DF (3)	local	--	--	--	ft/sec ²	Gravitational acceleration (local variable used in AVERAGE_G_INTEGRATOR).

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
IGR1	DF (3)	local	--	--	--	ft/sec ²	Gravitational acceleration (local variable used in AVERAGE_G_INTEGRATOR).
IMU_NAV_ACCEL_THRESH (V93A6710C)	SF	compool	MD	592	downlist	"g	IMU Navigation acceleration threshold value in "g's.
IN50_TO_EF	DF (3,3)	local	--	--	--	--	Mean of 1950 to Earth-fixed Greenwich coordinate transformation matrix.
OPS_2_OR_8_INITIALIZE_COMPLETE (V90X1242X)	B	compool	--	--	--	--	Signal to MSC indicating that initialization of user parameter state propagation is complete.
IR_AV	DF (3)	local	--	--	--	ft	Position vector (local variable used in AVERAGE_G_INTEGRATOR).
IR_AVGG (V95H0185C -7C)	DF (3)	compool	--	--	downlist	ft	Current Orbiter position vector updated by user parameter propagator.
IR_EF (V95H0155C -7C)	DF (3)	compool	--	--	--	ft	Orbiter position vector in Earth-fixed coordinates.
IR_RESET (V90H0235C -7C)	DF (3)	compool	--	--	--	ft	Copy of filter updated Orbiter position vector for user parameter propagator reset.
IR_TARGET (V95H0862C -4C)	DF (3)	compool	--	--	downlist	ft	Position vector of the target vehicle updated by the user parameter propagator.
IR_TV_RESET (V90H1383C -5C)	DF (3)	compool	--	--	--	ft	Copy of filter updated target position vector for user parameter propagator reset.
IT_IMU (V95W0901C)	DF	compool	--	--	downlist	sec	Current time tag snapped from the IMU SOP (IMU SOP name T_IMUS_GA M/SID V95W0002C).

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
IT_RESET (V90W1386C)	DF	compool	--	--	--	sec	Copy of time tag of filter update of state vectors for user parameter propagator reset.
IT_SEC GMT (V95W3890C)	DF	compool	--	--	--	sec	Time in seconds since Greenwich midnight of the reference day.
IT_STATE (V95W0200C)	DF	compool	--	--	downlist	sec	Time tag for current user parameter state vector.
UPP_USE IMU DATA (V95X0889X)	B	compool	IV	OFF	downlist	--	Flag indicating IMU data are to be used in integration (ON) in UPP.
IV_AV	DF (3)	local	--	--	--	ft/sec	Velocity vector (local variable used in AVERAGE_G_INTEGRATOR).
IV_AVGG (V95L0190C -2C)	DF (3)	compool	--	--	downlist	ft/sec	Velocity vector of Orbiter updated by the user parameter propagator.
IV_EF	SF (3)	local	--	--	--	ft/sec	Orbiter velocity vector in Earth-fixed coordinates.
IVFLIV_PRED	B	compool	HC	0	--	--	Venting flag for target vehicle prediction and for UPP state prop.
IV_IMU SNAP (V95L0898C -900C)	DF (3)	compool	--	--	downlist	ft/sec	Current snapped accumulated IMU velocity obtained from the IMU SOP (IMU SOP name <u>V</u> _IMU_CURRENT M/SID V90L2557 -9C).
IV_IMU OLD (V95L0210C -2C)	DF (3)	compool	--	--	--	ft/sec	Previous accumulated IMU velocity.
IV_IMU RESET (V90L0247C -9C)	DF (3)	compool	--	--	downlist	ft/sec	Copy of IMU accumulated sensed velocity for user parameter propagator reset.
IV_RESET (V90L0239C -41C)	DF (3)	compool	--	--	--	ft/sec	Copy of filter updated Orbiter velocity vector for user parameter propagator reset.

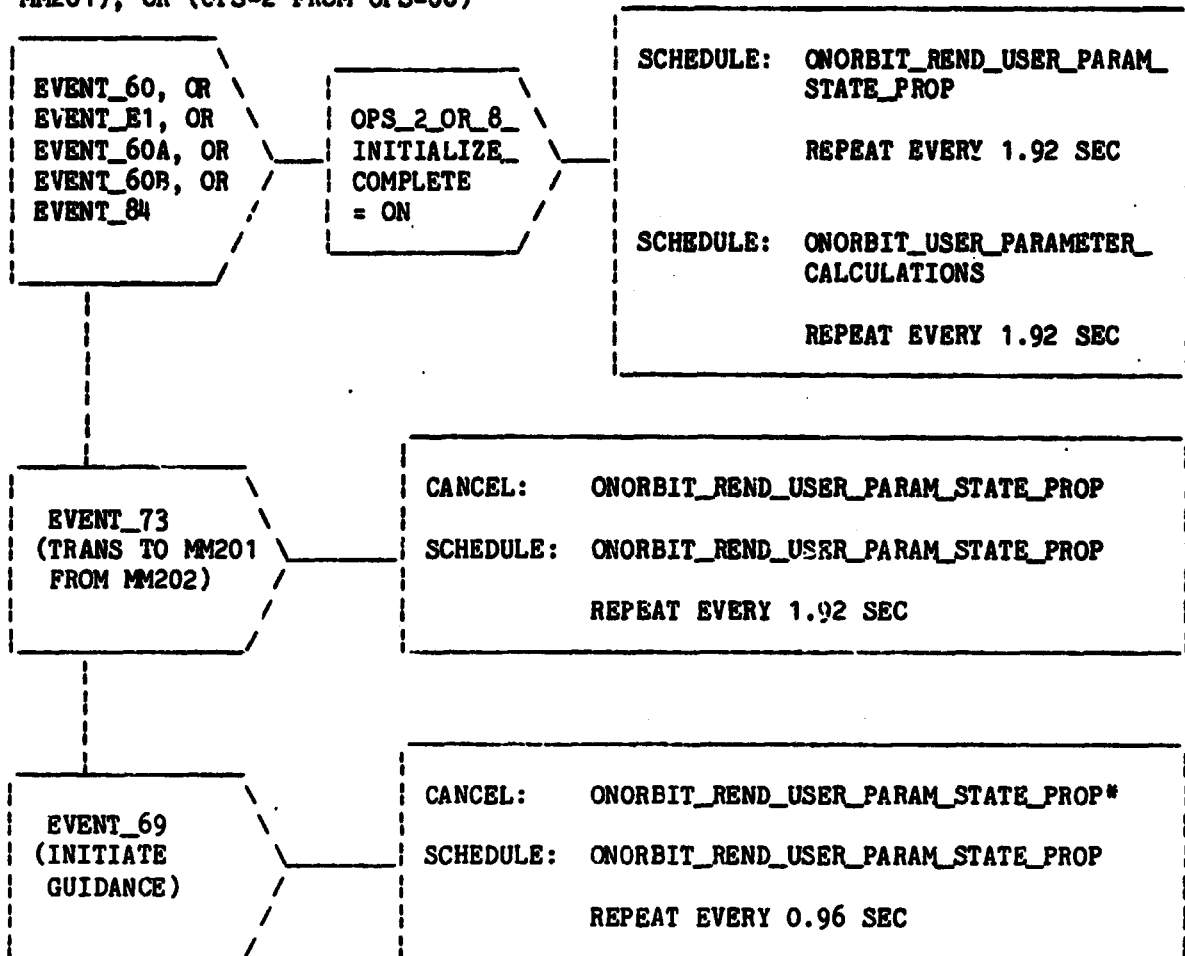

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
IV - RHO EP (V95L3884C -6C)	DP (3)	compool	--	--	--	ft/sec	Earth-fixed velocity vector for Shuttle.
IV - TARGET (V95L0867C -9C)	DP (3)	compool	--	--	downlist	ft/sec	Velocity vector of target vehicle updated by the user parameter propagator.
IV - TV RESET (V90L1380C -2C)	DP (3)	compool	--	--	--	ft/sec	Copy of filter updated target velocity vector for user parameter propagator reset.

VARIABLES LIST DEFINITIONS

CODE USED FOR VARIABLE DATA TYPE

F: Floating point quantity. An n-dimensional floating point vector will be denoted F(n). Similarly, an n x m floating point matrix will be denoted by F(n,m).

I: Integer quantity; I(n) will denote an n-dimensional integer vector

B. Bit, i.e., data having only values of 0 or 1

C: Character; C(n) will denote an n-dimensional character string

CODE USED FOR VARIABLE PRECISION

D: Double precision

S: Single precision; integer quantities are assumed single precision unless otherwise stated

VARIABLE LOCATION

COMPOOL: Variable value located in common storage, accessible by all functions.

LOCAL: Variable is used by one function only, and usable to other functions through call argument only

VARIABLE INITIALIZATION CATEGORY

blank: Display is vacant

C: Constant (unchanging)

DD: Design dependent

HC: Hard coded

MD: Mission dependent (I-LOAD)

VARIABLE INITIAL VALUE

Initial operation sequence computer inputs

PRECEDING PAGE BLANK NOT FILMED

VARIABLE UPLINK AND DOWNLIST STATUS

UPLINK: Variable is an uplink item

DOWNLIST: Variable is a downlist item

UNITS DEFINITIONS

deg: angular measurement, degrees

ft: feet

lb: pounds

n.d.: non-dimensional

rad: radian

sec: time measurement, seconds

Slugs: mass measurement, slugs

Vary: Units have different values which depend on variable use

VARIABLES LIST

VARIABLES LIST DEFINITIONS

CODE USED FOR VARIABLE DATA TYPE

F: floating point quantity; an n-dimensional floating point vector will be denoted $F(n)$; similarly, an $n \times m$ floating point matrix will be denoted by $F(n,m)$

I: integer quantity; $I(n)$ will denote an n-dimensional integer vector

B: bit, i.e., data having only values of 0 or 1

C: character; $C(n)$ will denote an n-dimensional character string

CODE USED FOR VARIABLE PRECISION

D: double precision

S: single precision. Integer quantities are assumed single precision unless otherwise stated.

VARIABLE LOCATION

COMPOOL: Variable value located in common storage, accessible by all functions

LOCAL: Variable is used by one function only, and usable to other functions through call argument only

VARIABLE INITIALIZATION CATEGORY

blank: display is vacant

C: constant (unchanging), Level A

DD: design dependent

HC: hard coded

MD: mission dependent (I-Load)

VARIABLE INITIAL VALUE

Initial operation sequence computer inputs

PRECEDING PAGE BLANK NOT FILMED

VARIABLE UPLINK AND DOWNLIST STATUS

UPLINK: variable is an uplink item

DOWNLIST: variable is a downlist item

UNITS DEFINITIONS

deg: angular measurement, degrees

ft: feet

lb: pounds

n.d.: non-dimensional

rad: radian

sec: time measurement, seconds

slugs: mass measurement, slugs

vary: units have different values which depend on variable use

VARIABLES LIST

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlink	Units	Description
COV_COR_UPDATE (V96H1290C -6C)	SF (7)	compool	MD	--	uplink	vary	Vector of correlation coefficients associated with UUV standard deviations (SIG_UPDATE) used for Orbiter position/velocity covariance initialization (ground update).
DO_OV_UPLINK (V90X4754X)	B	compool	--	OFF	--	--	Flag indicating (ON) that data has been uplinked for Orbiter state vector update.
DO_TV_UPLINK (V90X4757X)	B	compool	--	OFF	--	--	Flag indicating (ON) that data has been uplinked for target state vector update.
R_GND (V96H3500C -02C)	DF (3)	compool	--	--	uplink	ft	Uplink Orbiter position vector (MSD).
R_TV_GND (V96H1277C -79C)	DF (3)	compool	--	--	uplink	ft	Uplinked target vehicle position vector at T_TV_GND.
SIG_UPDATE (V96H1284C -9C)	SF (6)	compool	MD	--	uplink	--	Vector of standard deviations for Orbiter position/velocity covariance initialization (ground update).
T_GND (V96H3520C)	DF	compool	--	--	uplink	sec	Uplinked time tag of Orbiter state vector (R_GND, V_GND).
T_TV_GND (V96H1283C)	DF	compool	--	--	uplink	sec	Uplinked target state time tag.
V_GND (V96L3510C -12C)	DF (3)	compool	--	--	uplink	ft/sec	Uplinked Orbiter velocity vector.
V_TV_GND (V96L1280C -82C)	DF (3)	compool	--	--	uplink	ft/sec	Uplinked M1950 target vehicle velocity vector at T_TV_GND.
MLS_AVAIL_PSL	B	compool	MD	--	--	--	MLS available discrete for primary and secondary runways.
MLS_AVAIL_SSL	B	compool	MD	--	--	--

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlink	Units	Description
RUNWAY_ALT	SF (18)	compool	ND	--	--	ft	Altitude above reference ellipsoid of runway reference point for maxi table runways.
RUNWAY_ALT_ASL	SF	compool	ND	--	--	ft	Altitude above reference ellipsoid of runway reference point for primary, secondary, and alternate runways.
RUNWAY_ALT_PSL	SF	compool	ND	--	--	ft	
RUNWAY_ALT_SSL	SF	compool	ND	--	--	ft	
RUNWAY_NAME	C (18)	compool	ND	--	--	--	Name of landing site in maxi table.
RUNWAY_NAME_PSL	C	compool	ND	--	--	--	Name of landing site in mini table for primary, secondary, and alternate runways.
RUNWAY_NAME_SSL	C	compool	ND	--	--	--	
RUNWAY_NAME_ASL	C	compool	ND	--	--	--	
RW_AZIMUTH	SF (18)	compool	ND	--	--	rad	Bearing from true north of runway coordinate system -X axis for maxi table runways.
RW_AZIMUTH_ASL	SF	compool	ND	--	--	rad	Bearing from true north of runway coordinate system -X axis for primary, secondary, and alternate mini table runways.
RW_AZIMUTH_PSL	SF	compool	ND	--	--	rad	
RW_AZIMUTH_SSL	SF	compool	ND	--	--	rad	
LAND_SITE_NO (V96U1207C)	SI	compool	--	--	uplink	--	Landing site table slot (1 to 18 - maxi, 19 to 21 - mini).
ALT_ABOVE_ELLIPSOID	SF (10)	compool	ND	--	--	ft	Height of TACAN site above reference ellipsoid in mini table.
ALT_ABOVE_ELLIPSOID IFAXI	SF (50)	compool	ND	--	--	ft	Height of TACAN site above reference ellipsoid in maxi table.

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
BIAS_TAC_BRG	SF (10)	compool	MD	--	--	rad	Bias in TACAN bearing in mini table.
BIAS_TAC_R	SF (10)	compool	MD	--	--	ft	Bias in TACAN range in mini table.
LATITUDE_GEODETC	SF (10)	compool	MD	--	--	rad	Geodetic latitude at TACAN site in mini table.
LATITUDE_GEODETC_MAXI	SF (50)	compool	MD	--	--	rad	Geodetic latitude at TACAN site in maxi table.
LONGITUDE_EAST	SF (10)	compool	MD	--	--	rad	Longitude at TACAN site in mini table.
LONGITUDE_EAST_MAXI	SF (50)	compool	MD	--	--	rad	Longitude at TACAN site in maxi table.
MAGNETIC_VARIATION	SF (10)	compool	MD	--	--	rad	Magnetic variation of TACAN site in mini table.
MAGNETIC_VARIATION_MAXI	SF (50)	compool	MD	--	--	rad	Magnetic variation at TACAN site in maxi table.
MSL_ABOVE_ELLIPSOID	SF (10)	compool	MD	--	--	ft	MSL correction to reference ellipsoid at the TACAN site in mini table.
MSL_ABOVE_ELLIPSOID_MAXI	SF (50)	compool	MD	--	--	ft	MSL correction to reference ellipsoid at the TACAN site in maxi table.
TAC_ID	SI (10)	compool	MD	--	--	--	TACAN channel number in mini table. Positive for x-mode. Negative for y-mode.
TACAN_ID_MAXI	SI (50)	compool	MD	--	--	--	TACAN channel number in maxi table. Positive for x-mode. Negative for y-mode.

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
!ALT ABOVE ELLIPSOID_UL (V96H1220C)	SF	compool	--	--	uplink	ft	Height of uplinked TACAN site above reference ellipsoid.
!BIAS TAC BRG UL (V96H1223C)	SF	compool	--	--	uplink	rad	Uplinked TACAN bearing bias.
!BIAS TAC R UL (V96H1224C)	SF	compool	--	--	uplink	ft	Uplinked TACAN range bias.
!LATITUDE GEODETIC_UL (V96H1218C)	SF	compool	--	--	uplink	rad	Geodetic latitude at uplinked TACAN site.
!LONGITUDE EAST_UL (V96H1219C)	SF	compool	--	--	uplink	rad	Longitude of uplinked TACAN site.
!MAGNITUDE VARIATION_UL (V96H1222C)	SF	compool	--	--	uplink/ downlist	rad	Magnetic variation at uplinked TACAN site.
!MSL ABOVE ELLIPSOID_UL (V96H1221C)	SF	compool	--	--	uplink/ downlist	ft	Altitude of mean sea level above reference ellipsoid at uplinked TACAN site.
!DO TACAN SITE UPLINK (V95X1275X)	B	compool	--	--	uplink/ downlist	--	TACAN site uplink command.
!TAC SITE NO (V96J1216C)	SI	compool	--	--	uplink/ downlist	--	TACAN site table slot number.
!TACAN ID UL (V96J1217C)	SI	compool	--	--	uplink/ downlist	--	Channel/mode identifier for uplinked TACAN site.
!BUFFER_B	SF (3)	local	--	--	--	lbs	Buffer area associated with VENT/RCS vector uplink.
!BUFFER_C	SF (7)	local	--	--	--	--	Buffer area associated with covariance matrix uplink.

VARIABLES LIST

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
IBUFFER_C	SP	local	--	--	--	--	Buffer location associated with drag model correction factor.
IBUFFER_O	SP (2)	local	--	--	--	sec	Buffer area associated with Vent/RCS ON-OFF times uplink.
IBUFFER_R	DF (3)	local	--	--	--	ft	Buffer area associated with Orbiter state position vector uplink.
IBUFFER_RT	DF (3)	local	--	--	--	ft	Buffer area associated with target vehicle position vector uplink.
IBUFFER_S	SP (6)	local	--	--	--	ft,ft/sec	Buffer designations for UVW standard deviations associated with covariance matrix uplink.
IBUFFER_T	DF	local	--	--	--	sec	Buffer location associated with Orbiter state vector uplink (time tag).
IBUFFER_TT	DF	local	--	--	--	sec	Buffer location associated with rendezvous vehicle state vector uplink (time tag).
IBUFFER_V	SP (3)	local	--	--	--	ft/sec	Buffer area associated with Orbiter state vector uplink (velocity).
IBUFFER_VT	SP (3)	local	--	--	--	ft/sec	Buffer area associated with target vehicle state vector uplink (velocity).
IKFACTOR (V9608173C)	SP	compool	MD	--	uplink	--	Drag model correction coefficient.
TOP_CODE	SI	compool	--	--	uplink/ downlist	--	7-BIT string code to define command load uplink type.
ITPOFF (V9608178C)	DF	compool	MD	-	uplink/ downlist	sec	Vent/RCS off time.

VARIABLES LIST

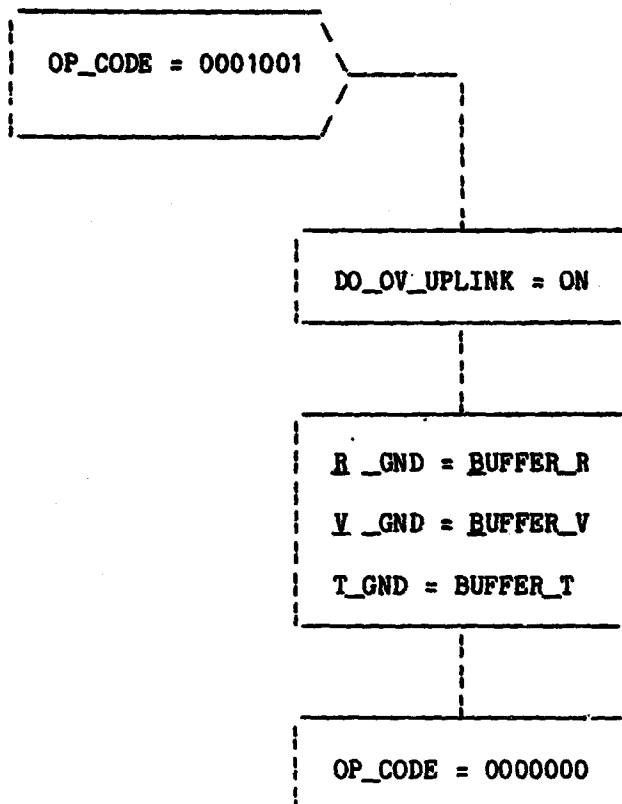

Variable name (M/S ID)	Precision & type	Compool or local	Initial- ization category	Initial value	Uplink/ downlist	Units	Description
TPON(V96W8177C)	DF	compool	MD	--	uplink downlist	sec	Vent/RCS on time.
VFORCE(V96U8174C -76C)	SF (3)	compool	MD	--	uplink downlist	lbs	Vent/RCS body force vector.
PRI_MAXI_UL (V96U8281C)	SI	compool	--	--	uplink/ downlist	--	Runway selection index for maxi table to primary runway data transfer.
SEC_MAXI_UL (V96U8282C)	SI	compool	--	--	uplink/ downlist	--	Runway selection index for maxi table to secondary runway data transfer.
ALT_MAXI_UL (V96U8283C)	SI	compool	--	--	uplink/ downlist	--	Runway selection index for maxi table to alternate runway data transfer.
DO_GUID UPLINK (V96U8280CB)	B	compool	--	--	uplink/ downlist	--	Flag indicating (ON) that landing site selection parameters have been uplinked.
PRI_MAXI_SELECT	SI	compool	--	19	--	--	Runway selection index for maxi table to primary runway data transfer.
SEC_MAXI_SELECT	SI	compool	--	20	--	--	Runway selection index for maxi table to secondary runway data transfer.
ALT_MAXI_SELECT	SI	compool	--	21	--	--	Runway selection index for maxi table to alternate runway data transfer.
ITEM1_IN	B	compool	--	OFF	--	--	Maxi table to primary runway transfer discrete.
ITEM2_IN	B	compool	--	OFF	--	--	Maxi table to secondary runway transfer discrete.
ITEM3_IN	B	compool	--	OFF	--	--	Maxi table to alternate runway transfer discrete.

APPENDIX G

INTERFACE DIAGRAMS FOR THE ONORBIT/RENDEZVOUS
NAVIGATION SEQUENCER PRINCIPAL FUNCTION, THE
ONORBIT/RENDEZVOUS NAVIGATION PRINCIPAL FUNCTION
AND THE ONORBIT PRECISION STATE PREDICTION
PRINCIPAL FUNCTION

PRECEDING PAGE BLANK NOT FORN

This appendix provides supplementary interface information concerning the following principal functions:

- Onorbit/Rendezvous Navigation Sequencer
- Onorbit/Rendezvous Navigation
- Onorbit Precision State Prediction

The intent of this appendix is to provide block diagrams for each principal function in order to supply the following information:

- a. The constituent subfunctions of each principal function.
- b. A calling diagram for each subfunction in each principal function.
- c. The interrelationship of the principal functions.

The information contained in this appendix is intended to be supplementary only.
